# 1 Project Background

---

## 1.1 Introduction

---

The field of home automation systems is a young and expanding market. Smart homes are buildings which are equipped with devices and sensors that can communicate with and control one another. Devices are connected through a network and act as an Internet of Things (IoT) <sup>1</sup>. As home automation becomes more popular with consumers, many companies are creating a wide variety of sophisticated devices. These companies commonly sell complete home automation systems, which contain everything needed to easily install and control their devices in a home. However, these home automation systems may require some level of technical knowledge and manual configuration in order to perform useful tasks. Some large commercial systems even require a technician to install the system in a home <sup>2</sup>. The complexity of installation and management, as well as the inflexibility of smart home configurations, are barriers preventing the technology from being adopted by the general public <sup>3</sup>.

Existing home automation systems often come pre-programmed with behaviours for specific devices. Creators of smart devices attempt to anticipate common behaviours that users want in their smart homes, and allow users to select these behaviours from a list of options. While this approach makes management of smart devices easy, it does not allow for customizable behaviour.

In order to make their systems more flexible, home automation systems often include the ability to create rules-based configurations. While this increases the flexibility of such systems, configuring a rules-based automation system can be complex and difficult to manage. Such systems are also often accompanied by a complex user interface.

The problem of creating a home automation system that is both customizable and easy to manage prevents adoption of home automation by consumers. The solution proposed by this project is to use machine learning in a home automation system to reduce the complexity of installing and customizing a smart home through a simple user interface.

## 1.2 Accomplishments

---

### Discovery of Devices

The user is able to add devices to the system by connecting them to the network and following the discovery sequence. Discovery is different for different devices and protocols. The system is able to automatically discover Z-Wave devices using the OpenZWave library. Once a device is discovered it is registered to the system.

### Device Displayed in User Interface

All devices that are registered in the system are visible from the user interface. The remote web client provides observability for the specific devices in the system as well as their currently reported status. Some basic metadata including name, manufacturer and protocol is also displayed to the user.

### Device Controlled through User Interface

All devices that are visible in the user interface which have a controllable attribute, such as the brightness level on a light bulb, can be controlled. The method for controlling these attributes depends on the type of the data being changed. For example, a binary value such as On/Off is controlled with a toggle button, the volume of a speaker is controlled with a slider, and the colour of a light bulb is controlled with a colour picking graphic.

### Events Displayed in User Interface

The user interface currently uses push notifications to receive events as they are logged in the system. These events are generated automatically by the devices connected to the system. These events are then immediately displayed to the user in real time on a live updating event feed.

### Discovery of Devices from User Interface

The user interface provides a mechanism for launching an automated discovery probe. This process kicks off discovery for any devices to be added to the system. If any new devices are added to the system during this process, the user is notified and the user interface is updated.

### Record Training Session

The user is able to create a behaviour which it wants the system to learn. They are then able to start a training session for this new behaviour. While a training session is in progress, all device events that occur are associated to that session. The result of this training is a model which can be used to make a basic decision.

## 1.3 Overview of Report

---

This report outlines the details of the Aria project, illustrating the design and development of the system. It provides the technical background and details about the decisions made in its construction. The report also outlines the engineering practices used to work effectively in a team to complete this project.

## 2 Engineering Project

---

### Health and Safety

---

At the beginning of the project, our team was investigating the feasibility of building our own custom smart devices, such as a lamp or motion sensor, by using a microcontroller to enable wireless capabilities. However, while investigating this, we discovered that constructing many of these devices would require working with high voltages. As stated in section 6.12 of the Laboratory Health and Safety manual, "Only trained, qualified personnel may repair or modify electrical or electronic equipment" <sup>4</sup>. Our team is composed of four software engineering students, none of which are adequately trained to work with high voltages. This was a dominant factor in our decision to abandon the idea of using custom smart devices and to instead use device manufactured by third parties.

No work was performed in a lab environment, so there were no other personal safety concerns during the duration of this project.

### 2.1 Engineering Professionalism

---

#### General Principles

An important aspect of engineering is communication. Throughout the course of this project, different levels of communication with different audiences were required. The most prevalent communication task was internal. Working in a group effectively demands clear and regular communication about ideas, project direction, and immediate goals to work towards. The process used to accomplish this is discussed later in detail. Strong communication skills are an important part of a larger engineering topic, which is the ability to work in a team.

Part of being an engineer is the ability to work in a professional manner regardless of personal issues which may arise. An engineer is responsible for improving the quality of work their team produces. Our project group has worked towards this by developing an atmosphere where everyone feels comfortable voicing their opinions, giving and receiving critical feedback, and feels like they are making a useful contribution to the overall goals of the team.

With the idea of keeping a clear project direction in mind, our team holds weekly scrums. This is when we collectively decide what goal is for the next week of development, working towards a more long term goal. Each team member discusses the work they have been doing and what they plan to accomplish in the upcoming week. Once this meeting is completed, our team drafts an email together to inform our project supervisor of our plans for the next week of development.

Part of the challenge of communication in engineering is identifying the audience and tailoring the content to match their level of technical understanding. Our team was responsible for producing an oral presentation to demonstrate to a faculty member the purpose and status of our project at that time.

#### Future Concerns

An area of engineering professionalism which future groups developing this project may need to investigate is the idea of intellectual property. Under the Copyright Act in Canada, computer software is labeled and protected as a literary work and is protected automatically <sup>5</sup>. This means that anyone who is not an owner the copyright cannot produce copies of this software. However, depending on the future development of the machine learning component, further protection may be required in the form of patents.

A software patent can only be obtained for an implemented feature which is "new, useful, and non-obvious" <sup>6</sup>. If the machine learning aspect of this project improves to the point where there is a systematic way to learn desired behaviours with a high degree of accuracy and precision, it may be worth investigating patent protection. Unlike a copyright, a patent must be applied for and approved.

### 2.2 Project Management

## 3 Technical Sections

---

### 3.1 Background

---

#### 3.1.1 Technical Terminology

In order to describe the Aria system and the field of smart home automation, technical terminology will be required. This section outlines a set of technical terms and phrases that will be used to describe this field of technology.

##### Real-Time System

A real-time system is a computing system that processes input data within a millisecond window such that the output is ready virtually immediately <sup>7</sup>. Real-time systems will be used as smart devices as well as computing devices in the Aria system.

##### Embedded Device

An embedded device is a special purpose computing device that is encapsulated by the device it interacts with or controls <sup>8</sup>.

##### Smart Home

A smart home is an environment that contains sensors and actuators that can be controlled remotely <sup>9</sup>.

##### Machine Learning

Machine learning is an process for a computer to modify its behaviour based on its inputs <sup>10</sup>.

##### Internet of Things (IoT)

The internet of things (IoT) is a term used to describe a network of embedded devices that send and receive data via the internet <sup>11</sup>.

##### Smart Hub

A smart hub is an embedded device that all smart home devices interact with as a central point of communication.

##### Device Scenes

A software configuration of smart devices in a home that outlines specific behaviours of each device. Scenes are used by smart homes to recreate a specific setups that a user has configured <sup>12</sup>.

##### If This Then That (IFTTT)

An algorithm that causes a reaction when a set of criteria are met. If the criteria are met then an action is performed.

#### 3.1.2 Problem Background

The expanding IoT market has sparked a rush of companies to introduce smart home automation platforms to market. These new smart home system systems offer rich features but have a complex setup process or complex automation options. The usability of these features limit the access of home automation to a technical audience. To fully understand the user experience limitations, existing smart home systems need to be examined. This section details a number of existing home automation systems, outlining their major features and pitfalls. For the complete research on these automation systems, please refer to [Appendix A](#).

The smart home automation systems examined in this research included [Insteon](#), [Wink](#), [Samsung SmartThings](#) and [Apple HomeKit](#). While there are several other smart home systems, this collection provides a general overview of the market of automation systems. With the exception of Apple's HomeKit, all of the automation systems are based on the same architecture. Each system has its own smart hub that smart devices are paired with in order to be controlled through an app or web browser. The HomeKit differs from these systems by simply connecting devices directly to a user's smart phone so it can be controlled through their app. While the architecture of these companies are similar, their methods for device pairing, user configuration and operation differ. These features of smart home automation all try to solve the same technical issue, bringing a complex, technical world of device communication and configuration to non-technical users. These companies must bring the technical tasks of device pairing, device configuration and user configuration to a non-technical audience.

The process of device pairing involves connecting a device to the smart hub to be used by the system. There are a number of technical issues when establishing this connection. The device will need to know the medium to communicate with, the protocol to use for communication and the location of the hub in the network. This process requires a significant amount of technical understanding to be able to perform. If this task is left to the user then the system's usability is significantly reduced to a narrow portion of the public by isolating it to a technical audience. Automating this process could significantly reduce this technical requirement and broaden the usability of the system.

After the device has been paired with the smart hub, it needs to be configured to provide the hub with meaningful information. This configuration process is typically vendor or device specific. Often, this process requires managing technical properties of the device which again isolates a non-technical user. This process too could be automated to an extent, relieving the user from this technical requirement. Using device defaults and providing a simple, non-technical mechanism for configuring these devices would also reduce the technical requirements for this task.

The system must also provide automation features for a user to configure their smart home. This process too can be over complicated by not providing clear, meaningful representations of the devices in their home for them. The system must provide a simple method for monitoring and controlling their environment. Having clean, user friendly controls will allow the system be usable by any non-technical user.

Finally, a smart home must provide some form of scheduled configuration. This configuration should set a device to a specific state at a desired time. This is yet another feature that needs to be simplified in order to cater to a non-technical audience. The automation of this process is much more advanced then automating any other task in the system as it involves prediction of user configuration. Having this process automated would be the final component on the path to offering a smart home to a non-technical user.

Eliminating the technical tasks required to setup and utilize a smart home would make this technology available to a non-technical user and could expand the market of smart home automation.

## 3.2 Project Details

---

### 3.2.1 Overview

#### Introduction

The Autonomous Real-Time Interactive Architecture (Aria) will allow a homeowner to set up a collection of devices in their home which will automatically control their environment and automate common tasks. Task automation in the system will not require any user configuration, instead tasks will be automated based on the user's interaction with devices in the system.

The system will consist of a hub device with a simple interface that a homeowner can connect to their home network. After connecting the hub, the homeowner can add enabled devices for the system to control by simply connecting them to the network. As new devices are connected, their input will be used to make more predictive decisions about user behaviour.

#### Product Functions

To ensure a non-technical user can utilize the system, the system must be easy to use and highly interactive. The system will provide a smart hub that will be the base of computation and communication for all other components in the system.

The system will have many different smart devices. These devices can be sensory inputs or controls for a task. To allow for expansion of the automation system, it must be able to accept new devices. The system must then retain its previous model of the user's interactions but add in the new device as evidence for predicting future behaviours. For example, a system might include a light sensor, thermostat and curtain puller. If the ambient light outside was to drop and the user closed the curtains then the system might predict that a change in light corresponds to that action. If the user then changes the temperature, the system may relate light to temperature as well. If later a temperature sensor was added to the system and the user changes the temperature when it is too cold, the system will use this information to predict future actions.

To be able to monitor and control the system, the learning hub must be controllable using a graphical interface. This interface will be provided in the form of a web interface and allow the user to view the state of the system and manually control any connected device. This interface can be used for manually configuring desired behaviours as well as for enabling the learning mode of the system. The interface must allow the user to view the state of all devices in the system as well as view their recorded interactions.

### 3.2.2 System Design

This design illustrates the configuration that the Aria system will be used in. The smart hub will be the main point of communication for all smart devices in the network. The user will use the web interface to communicate to the smart hub for all commands. If a command is meant to be directed to smart device in the network then the message will first be sent to smart hub before being relayed to the specific device.

The design for this system will need to consider the requirement that multiple devices will need to connect to a single smart hub. The hub will also need to support concurrent connections with users, as more than one may wish to have access at any given time. These features present some hardware requirements that must be satisfied. The physical smart hub must have external interfaces for communicating to multiple devices and must support concurrent processes. The communication protocol to interface with the smart devices themselves must also be considered as it must work on low power embedded devices with short to medium range connections. Fortunately, the data transfer rate requirements for this system will be minimal as only small state transfers of sensor readings or device commands must be communicated.

The smart hub's requirements limits the devices that can be utilized for its purpose. A comprehensive breakdown of embedded device specifications can be viewed in [Appendix B](#). The research compares a number of miniature computing devices for the role of the smart hub including various Arduinos, Raspberry Pis and Beagle Bones. Due to the requirement of concurrent processes, a number of the computing devices were eliminated. The eliminated computing devices were all embedded machines that only offered a single core processor with no operating system or concurrency mechanisms. It would only be fair to call the remaining devices miniature computers as they all support light weight operating systems with concurrency. Of these devices, the Raspberry Pi 3 Model B has the greatest performance specifications and would be able to perform the required tasks for the smart hub.

When considering the communication protocols to support for the smart home system, efficiency, range and interoperability must be considered. Leading industry communication protocols including WiFi, Bluetooth, ZigBee, Z-Wave and Insteon were examined for these requirements. The full details of the research of these communication protocols can be seen in [Appendix C](#). While the Aria system is designed to support many protocols, a single one needed to be chosen as an initial, prototype protocol. For this task, Z-Wave was chosen as it provides the most standardized method for device communication of any of the protocols. Z-Wave is both a hardware and software level specification that integrates a wide spectrum of devices over a single, standard interface. For this reason, it was selected as the primary device communication for the Aria system.

The remainder of the technical section outlines the details of the software development and implementation of the smart hub. Included in this analysis is the details of the remote client interface for controlling the smart hub and its connected devices.

### 3.2.3 Scenarios

In order to better understand the motivations for using the learning home automation system, scenarios outlining expected

behaviours have been developed. These scenarios are designed to examine use cases of the Aria system. The intent of these scenarios is to explore what ways the system could be used, uncover potential areas of concern and to help reason about the technical operations of the system. In particular, each scenario has been coupled with a set of example data that will be used to better understand the data requirements of the system. These samples scenario sequences can be found in [Appendix G](#).

The following scenarios are isolated example usages of the system. Each provides a brief description of the scenario, followed by the details about the interactions and features the scenario will require from the system

## Music Automation

### Background

Smart home automation should make your life easy and fun. Imagine a group of people arrive at your house for a party. Your home automation system has learned how to set up your environment to give you the best experience possible. The lights dim, the temperature goes down, and the music goes up. Your home is now ready for your guests! The sample data for this scenario can be found in [Appendix G-1](#).

### System Interaction

The home automation system will be able to interact with a music system. The remote interface will allow the user to turn on and off music and control the system volume. The system may also be able to control the specific speakers that are active and playing music.

The user may choose to schedule the operation of music within the home to start at a certain date or time. Alternatively, the user may train the system that when many people enter the home then music should start playing at a certain volume. This could be accomplished by entering training mode, having a large number of people enter the room and then turning on music. Motion sensors would be required to measure the occupancy of the home to enable this learning.

Using a similar method to the music training, the user could train the system to tune the temperature, lights, and any other devices they wish. This could indicate to the system that when there are many people in the home, all of the trained systems should be activated.

### System Requirements

To be able to monitor the home, the following sensors may be of interest. These sensors will be use to monitor the occupancy of the home as well as determine the noise level of the home to appropriately adjust the music.

Sensor	Usage
Beam Motion Sensor	2 Beam sensors in series can be used to estimate occupancy
Audio Sensor	Audio sensor for tuning music volume to the atmosphere
PIR Motion Sensor	A PIR motion sensor can detect activity in a room

The system will require some devices to be able to produce the desired outputs. The following table lists example devices to allow this system to perform the tasks outlined in this scenario.

Device	Usage
Speakers	Controllable speakers for home configuration
Controllable Lights	Lights that can be controlled by the central system
Thermostat	Allows temperature to be adjusted

## Efficient Lights and Temperature

### Background

A smart home should reduce your energy bills and keep you comfy. During your work week, your home is left to cool during the day when no one is home. In the evening, before you arrive, the system heats the house to a comfortable temperature. As you arrive home, the lights automatically turn on in the rooms that you will enter. Later in the evening, the system cools the house to a comfortable sleeping temperature and dims the lights.

On the weekend, the house remains warm during the day while you are home. If you leave then to go to a store, the system turns off all the lights and lowers the temperature. When your arrive home again the system turns the lights back on and raises the temperature.

In the summer months, when it is more light outside, the system does not turn the home's lights on until later. In the winter months, the home turns the lights on earlier. The sample data for this scenario can be found in [Appendix G-2](#).

#### System Interaction

The system will need to interact with multiple sensors as well as light and temperature controllers. The remote interface will need to be able to display the state of all the sensors in the system. The remote will also need to offer control of the other devices in the system.

The system will also be able to be trained to obtain the desired output. To be able to have the lights turn off when the user leaves the room, the user could enter training mode with the lights on, leave the room and then turn off the lights. If this interaction was repeated then the system might learn this behaviour.

For the system to learn the desired temperature that the user desired, the learning process may be much longer. At different times of day the user will change the temperature. As environmental factors changes, the system will make these observations and use them to decide what the should be set to.

#### System Requirements

To enable light and temperature control, sensors will be needed to observe the system. The sensors will be needed to observe the ambient light and temperature of the home. There will also need to be sensors to determine the occupancy of the home. The following is a list of sensors that will be needed for this scenario.

Sensor	Usage
Light Sensor	Used to determine the amount of light in the home
Temperature Sensor	Need to observe the temperature of the home
Motion Sensor	Will provide information about the occupancy of the home

To enable this scenario, the system will need to be able to control a number of devices. The system will need to have control of the home's lights and thermostat. In addition to having the devices in the system, the system's user interface will need to provide control mechanisms for the device. The following is a list of the devices that will be needed and how they will be used in the system.

Device	Usage
Smart Lights	Lights that can be controlled through an API
Thermostat Controller	A device that can control the temperature through an API

### Coffee Automation

#### Background

Routine tasks done on a periodic schedule and can be automated by a smart process. Every morning you wake up and make a pot of coffee before you go about your day. Making a pot of coffee is a task that can be handled automatically by the smart home system. The system should learn when you wake up and make your coffee for you.

Let's imagine that on the weekend you don't make any morning coffee, the system should learn this behaviour and adapt during the days of the week. On a day that you are not at home, the system should not make any coffee either. The sample data for this scenario can be found in [Appendix G-3](#).

#### System Interaction

The system will need to be able to interact with a number of sensors to detect the user's presence. The system will also need to be able to communicate to a smart coffee maker so that it can observe when it is running as well as turn it off and on. The system will also need to be able to differentiate between the different days of the week and the time of day.

In order to train the system, the user could put the system into training mode and then get into bed. The user could then get out of bed and go directly to the kitchen and make a pot of coffee. The system could observe the user's leaving the bed with motion sensors and track that they are making coffee in a smart coffee maker.

#### System Requirements

To track the user's motion in the home, the system will need motion sensors. To be able to differentiate between the days of the week and time, the system will also need access to a clock and a calendar. The following is a list of sensors that will be required for this interaction.

Sensor	Usage
Motion Sensors	Used to track user movement throughout the home
Clock	Used to determine the time of day that the user makes coffee
Calendar	Used to determine what day of the week the user makes coffee

To be able to actually make the coffee, a smart coffee maker will be needed. This is the only smart device that will be required to automate this scenario.

## Effortless Home Lighting

### Background

A learning smart home should reduce the need to manually perform everyday environmental control tasks. The system should be able to take in information from multiple sensors and devices, and be able to make adjustments to the home environment based on that information.

The homeowner enters their home office on a bright afternoon, and the lights remain turned off. They continue working through the afternoon and into the evening. As the sun begins to set, the lights in the room turn on at a low intensity to maintain the current level of brightness. The lights continue to increase in brightness as the sun continues to set, without any interaction from the person in the room. When the homeowner exits the room, the lights shut off.

At the same time the following day, the home owner re-enters the office. The weather outside is dark and rainy. The lights turn on to a comfortable brightness level upon entry, and remain there as the home owner works into the evening again. Upon exiting the room, the lights shut off again. The sample data for this scenario can be found in [Appendix G-4](#).

### System Interaction

The system is required to combine information about the external environment with information about the homes internal environment. Simply tracking any one factor will not result in the system being able to perform this scenario, as the required device output does not correspond linearly to any one input.

Having the external environment be a factor in this scenario makes it hard to train the system to specifically do this, as you cannot easily control the external light levels. However, assuming the home owner keeps the light in the room at a certain level while the system is learning, the behaviour should be able to be learned.

### System Requirements

Two different sensors are needed for this scenario. A passive infrared sensor would be used to detect when there is someone present in a room. An ambient light sensor for inside the room will also be needed.

Sensor	Usage
Light	Used to determine the amount of light in a room
PIR	Will provide information about the occupancy of a room

To enable this scenario, the system will need to be able to change the brightness level of lights. The following is a list of the devices that will be needed and how they will be used in the system.

Device	Usage
Smart Lights	Lights that can be controlled through an API

## 3.2.4 Use Cases

In order to translate the scenarios into technical requirements for the Aria system, use cases were developed. These use cases outline the major functionality that is required by the Aria system. Figure outlines the use cases for the entire Aria system. Below are the descriptions of each use case for the system.

Name	<b>Install Hub</b>
Description	The user installs the learning hub in their home in order to enable automation of their smart devices.
Primary Actor	HomeOwner
Precondition	
Postcondition	
Flow	<ol style="list-style-type: none"> <li>1. User plugs hub into outlet and turns power on</li> <li>2. User connects hub to a home network using Ethernet</li> <li>3. Hub provides confirmation that system is online</li> </ol>

Name	<b>Add Device</b>
Description	Devices can be added to the system simply by powering them on and connecting to the network.
Primary Actor	HomeOwner
Precondition	A learning hub must be installed in the user's home
Postcondition	The device's state will now be used as input in learning mode. If the device contains an actuator, the actuator will be controlled by the learning hub in normal mode.
Flow	<ol style="list-style-type: none"> <li>1. User plugs in device and turns power on</li> <li>2. Device discovers network</li> <li>3. Hub discovers device and provides confirmation</li> </ol>

Name	<b>Enter Learning Mode</b>
Description	The user enters learning mode in order to indicate to the system that it should begin recording changes in the state of connected devices, without attempting to control them. Learning mode accomplishes the user's goal of configuring the system without manual programming.
Primary Actor	HomeOwner
Precondition	
Postcondition	The system saves changes in the state of connected devices
Flow	<ol style="list-style-type: none"> <li>1. User selects enter learning mode</li> <li>2. While the system is in learning mode, the system will record the user's interactions with connected devices.</li> <li>3. When the user selects normal mode or standby mode, the system exits learning mode.</li> </ol>

Name	<b>Enter Normal Mode</b>
Description	The user enters normal mode in order to instruct the system to begin controlling connected devices.
Primary Actor	HomeOwner
Precondition	
Postcondition	The system maintains control over connected actuators
Flow	<ol style="list-style-type: none"> <li>1. User selects enter normal mode</li> <li>2. System exits the currently active mode</li> <li>3. System begins controlling connected actuators, using the data collected during learning mode to infer the desired state of the system.</li> </ol>

Name	<b>Enter Standby Mode</b>
Description	The user enters standby mode in order to instruct the system that control over connected devices should be halted, and changes in the state of devices should not be accepted as learning data. Standby mode allows a user to control their devices under exceptional circumstances without learning the system to perform an incorrect task.
Primary Actor	HomeOwner
Precondition	
Postcondition	System does not accept learning data, System does not modify the state of devices
Flow	<ol style="list-style-type: none"> <li>1. User enters standby mode</li> <li>2. System exits the active mode</li> </ol>

Name	<b>Remove Device</b>
Description	Devices will stop recording when removed from the smart learning network. To remove the history of the device, the user can delete it using the remote interface.
Dependencies	<b>INCLUDE</b> Reset Device
Primary Actor	HomeOwner
Precondition	
Postcondition	System does not accept learning data, System does not modify the state of devices
Flow	<ol style="list-style-type: none"> <li>1. User disconnects device from the network</li> <li>2. If the user wishes to remove the device permanently, <b>INCLUDE</b> use case Reset Device</li> </ol>

Name	<b>Reset Device</b>
Description	States of the selected devices from before the reset are no longer used to infer states in normal mode.
Dependencies	
Primary Actor	HomeOwner
Precondition	
Postcondition	System does not accept learning data, System does not modify the state of devices
Flow	<ol style="list-style-type: none"> <li>1. User logs in to remote interface</li> <li>2. User selects a device</li> <li>3. User selects reset device</li> <li>4. System erases the saved historical states of the device</li> </ol>

### Training Use Cases

A subset of the behaviour required for the smart home behaviour is the training of the system. Training involves a user creating a behaviour they wish to train the system to perform, then by performing multiple training sessions, they can train it. This feature has a number of use cases associated with it which are depicted in Figure .

Name	<b>View Behaviours</b>
Description	Displays the saved behaviours in the system
Dependencies	
Primary Actor	WebUser
Precondition	
Postcondition	
Flow	1. User naviagtes to the training view 2. User is presented with a list of existing behaviours

Name	<b>Add Behaviour</b>
Description	Adds a new behaviour that can be trained in the system to the list of system behaviours
Dependencies	
Primary Actor	WebUser
Precondition	User is on the training view
Postcondition	User is on the details view for the new behaviour
Flow	<ol style="list-style-type: none"> <li>1. User selects "Add behaviour"</li> <li>2. User specifies a name for the new behaviour</li> <li>3. User saves behaviour</li> </ol>

Name	<b>Edit Behaviour</b>
Description	Allows user to modify the details of a behaviour and delete existing training sessions associated with it
Dependencies	
Primary Actor	WebUser
Precondition	User is on the training view
Postcondition	
Flow	<ol style="list-style-type: none"> <li>1. User selects a behaviour from the list of behaviours.</li> <li>2. Behaviour details view is opened.</li> <li>3. User can change the name of the behaviour.</li> <li>4. User is presented with a list of training sessions associated with the behaviour.</li> </ol>

Name	<b>Add Training Session</b>
Description	Adds a new training session to a behaviour. This allows a user to use event data to be associated with a desired behaviour
Dependencies	
Primary Actor	WebUser
Precondition	User is on the behaviour details view
Postcondition	User is on the details view for the new session
Flow	<ol style="list-style-type: none"> <li>1. User selects a behaviour from the list of behaviours.</li> <li>2. Behaviour details view is opened.</li> <li>3. User can change the name of the behaviour.</li> <li>4. User is presented with a list of training sessions associated with the behaviour.</li> </ol>

Name	<b>Start Training Session</b>
Description	Starts logging events and associating them to a particular training session
Dependencies	
Primary Actor	WebUser
Precondition	<ol style="list-style-type: none"> <li>1. User is on the details view for a session</li> <li>2. System is not currently running a training session</li> </ol>
Postcondition	<ol style="list-style-type: none"> <li>1. The active training session is indicated on the hub main view</li> <li>2. The system starts recording events and associating them with the training session</li> <li>3. Hub is in training mode</li> </ol>
Flow	<ol style="list-style-type: none"> <li>1. User clicks start session button</li> <li>2. View indicates that the training session is active</li> </ol>

Name	<b>Stop Training Session</b>
Description	Stops logging events and associating them to a particular training session
Dependencies	
Primary Actor	WebUser
Precondition	<ol style="list-style-type: none"> <li>1. User is on the details view for a session</li> <li>2. System is currently recording a training session</li> </ol>
Postcondition	<ol style="list-style-type: none"> <li>1. The training session is not longer marked as active on the hub main view</li> <li>2. The system no longer associated new events with the session</li> <li>3. Hub is in normal mode</li> </ol>
Flow	<ol style="list-style-type: none"> <li>1. User clicks stop session button</li> <li>2. View indicates that the training session is no longer active</li> </ol>

### 3.2.5 Non-Functional Requirements

#### Performance Requirements

##### Device Communication Range

Devices must be able to communicate wirelessly using the network. The range of communication must be sufficiently large that devices can be placed anywhere in an average home. The smart home devices will need to be capable of receiving and transmitting data using this network with enough range.

The distance between nodes in our system must be no more than 50 meters. The will allow for any protocol to communicate with the necessary nodes.

##### System Responsiveness

The system must readily adapt to environmental changes to be effective. When in learning mode, the system does not make any decisions and therefore has no responsiveness requirement. However, when the system enters playback mode it must make decisions as fast as environmental changes are received. This will ensure that the system is as responsive as possible when a user performs an action.

#### Security Requirements

##### Device Connection Security

All commands to devices must be authenticated to ensure that they are from an authorized source. This is in order to eliminate the possibility of malicious entities taking control of a home's devices.

### **Remote Interface Security**

Digital access to the hub's configuration interface must be secured using TLS 1.2 (RFC 5246) and HTTP basic authentication as described in RFC 2617. Use of these Internet Official Protocol Standards ensures that the system uses widely accepted authentication practices.

### **Quality Requirements**

#### **Learning Hub Reliability**

The learning hub is the center of communications and is responsible for interfacing with the system user. It must record data on some form of internal storage to log actions that have occurred as well as decisions that it has made. It is critical that the learning hub not lose its data as this would set the system back to its initial, untrained state. Precautions should be taken so that in the case of a system failure or power failure, the critical system data is preserved. Hub operations should be atomic and reversible should they fail.

The learning hub must also be online and available to record system events. If the learning hub is to go into a state faulty state then it should indicate this to the user. The system must provide a mechanism for resetting itself if errors are occurring.

#### **Device Reliability**

Devices in the system do not need to meet as high of a standard as the learning hub for reliability. However, devices should have some indicator when faults occur. Devices may be hard to access so any device that can be restarted should provide functionality for doing so from the remote interface. If this is not possible then as a minimum, the remote interface should indicate whether or not a device has encountered a fault or if it is no longer responding. Restarting a device in the network should then reconnect to the system and retain all of its history within the learning hub.

## **3.2.6 System Components**

The objective of this section is to present technical details about the implementation of the proposed solution. The section begins by introducing some of the fundamental concepts used throughout this project. Following these definitions is a component diagram showing the relationships between system components, as well as a description of each component and the interfaces that it provides. This section also includes a discussion of the architectural patterns that have been used, as well as the deployment of the system.

### **Domain Concept Definitions**

Event: An Event is an object that drives changes within the system. Events are generated asynchronously from several sources, including:

- Smart Devices
- User Interface
- Machine Learning Component

Several subtypes of events have been identified:

- User Command: An action on the user interface may generate an event that requires a change in the state of the system or a smart device.
- Sensor Value Change: A smart device that contains a sensor may generate an event to indicate that its value has changed.
- Device Discovery: Upon detection of a new device in the home, the system generates an event.
- Device Control: Device control events may be generated by either the User Interface or the Machine Learning Component.

### **Component Organization**

## Component Descriptions

### Exchange Server

As described in the Domain Concept Definitions, changes in the system are driven by events. Events may trigger updates to the user interface, changes to the state of smart devices, and machine learning decisions, among other actions. No single component contains the logic necessary to respond to every type of event. Additionally, some events may require a response from multiple components.

One solution to this problem is to allow every component to communicate with every other component. This is undesirable because it would lead to high coupling between components, reducing the modifiability of the system.

In order to avoid this high coupling between components, every component that must react to system events registers itself with a central Exchange Server component. Components send messages to the Exchange Server, rather than directly to other components, and the Exchange Server forwards these messages to the appropriate destination.

The Exchange Server component provides two interfaces: InternalMessaging and IPCMessaging. The InternalMessaging interface provides a way for components that are running in the same process as the Exchange Server to send and receive event messages. The IPCMessaging interface allows components that are running in different processes to send and receive messages from one another, using an IPC (InterProcess Communication) protocol. The IPC protocol is described in further detail in section [Appendix J-1](#). Details about individual implementing this component can be found in [Appendix H-1](#).

### Event Logger

The event logger listens to all event messages and transforming them into the appropriate format to be stored in the database. This data will be accessible by the remote client as well as the machine learning algorithm. The event logger consumes the

InternalMessaging interface provided by the Exchange Server, which allows it to receive all event messages and record them. The selection and design of persistent storage is discussed in [Appendix H-2](#).

### Machine Learning

This component is responsible for the system's autonomous control of devices. Based on the historical data recorded by the Event Logger, this component constructs a model of how the user expects their devices to behave.

This component uses the InternalMessaging interface provided by the Exchange Server to observe the current state of devices in the system. Based on these observations, this component can generate device control messages to change the state of devices.

### HTTP Gateway

The HTTP gateway is responsible for providing access to system data and business objects to a web client.

In addition to serving static HTML content, the HTTP gateway provides a RESTful API which supports AJAX requests from the web client. The basic functionality of the gateway is to marshal HTTP requests from the web client into messages that other components can respond to. The responses to these messages are then serialized into the JSON format that is usable by the web client.

The HTTP gateway also provides push event functionality. Some system events that are of interest to the user interface may not be generated in response to an HTTP request from the web client. In order to propagate these events to the user interface, the HTTP Gateway maintains a Websocket connection with the web client. Further details about the implementation of the HTTP Gateway can be found in [Appendix H-7](#).

### Device Adapter

Each smart device connected to the system communicates with the system hub and other devices using a device-specific protocol. Sensor events received using the device-specific protocol must be translated into a format that can be used by other system components. Device control messages from the system must also be translated into the device-specific protocol. The Device Adapter is responsible for this translation functionality; it adapts the device specific protocol used by devices to the uniform messaging interface used internally by the system.

For technical specification about the Z-Wave protocol supported by the system, please see [Appendix H-8](#).

## Architectural Patterns

This section discusses the architectural patterns that have been identified within the system. Each pattern is described by first presenting the problem that each pattern is intended to solve, in the context of this system.

### Layer Pattern

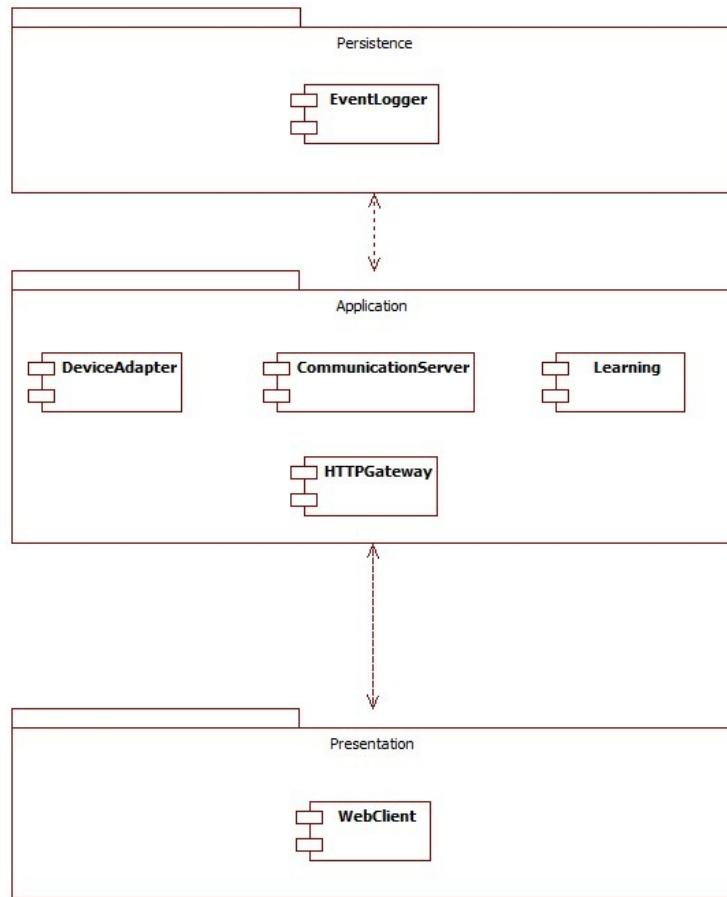

In order to allow for development on different parts of the code to proceed independently, it was necessary to introduce separation of concerns into the organization of components. This project makes use of the layer pattern to improve separation of concerns.

The components of this project are partitioned into three layers: Persistence, Application, and Presentation. This pattern is commonly known as a three-tier architecture for client-server applications.

The persistence layer is responsible for storing objects in a database. In the Aria system, the persisted objects are events and device metadata. The application layer is responsible for carrying out the business logic of the application and providing an interface to retrieve data. In the Aria system, this includes autonomous control of devices using machine learning.

The presentation layer is responsible for displaying information to the user, and providing the user with a way to control the system. In the Aria system, this layer is composed of HTML pages which make use of AJAX to retrieve data from the RESTful interface provided by the application layer.

The following diagram shows the organization of system components into a layered pattern.

### Client-Server and Broker Patterns

The decision to provide a user interface in the form of a web application imposed a client-server architecture on the project. Client-server is the architecture used by the web, so some form of client-server architecture is necessary in the project. The deployment diagram below shows the process distribution between client and server.

One architectural feature of note is the separation of the HTTP gateway component into a separate process from the application server. This design decision was made in order to improve the future usability of the system. An alternative solution considered during system design is to include both the application logic and HTTP server within a single process. The decision to separate the components into two processes was made following a comparison of the benefits of each approach:

#### Single Process Benefits

- Lower Overhead: Separation of a component into a separate process introduces overhead in communication between components
- Ease of Implementation: Interprocess communication can potentially introduce unnecessary complexity to the code.

#### Multi-Process Benefits

- Independence between the location of the HTTP server and the application logic. The web client does not need to know the location of the application server.
- Allows use of different technologies for the HTTP server and application logic.

The independence between the location of the HTTP server and application logic is ultimately the reason for separating the components into different processes. A common feature of existing smart home automation systems is the ability to control and monitor the home from a computer that is not currently inside the home. For example; a user can see whether their door is open or not from their work computer. Users expect this feature to be available from any commercial home automation system. While this is not currently a feature of the Aria system, the system design accounts for the fact that this is likely an essential feature in the future.

The ability to control the home remotely presents a technical challenge. In order for a web client that is not on the same LAN as the hub device to communicate with the hub directly, the user would need to configure port-forwarding on their router, modify their firewall configuration to allow for inbound HTTP requests, and configure a public, static IP address for their network. For even a

technical user this could be a daunting task. Given that the major requirement for the Aria system is usability, direct communication between a remote client and the user's Aria hub is clearly not an acceptable solution.

An acceptable solution to this problem is to make use of a Broker pattern, with the HTTP server acting as a broker for the application server. The web client can communicate with the HTTP server at a well-known public address, potentially hosted on a cloud computing platform, from any physical location. This server can then relay requests to the Aria hub within the user's home. The communication between the HTTP server and the system hub can use a mechanism that does not require special network configuration on the part of the user, such as WebSockets or HTTP long polling.

The extensibility and usability benefits of separating the HTTP and application servers into separate processes are worth the added complexity and overhead.

### **3.2.7 External Interface Requirements**

#### **User Interfaces**

##### **Remote Interface**

The remote interface will allow the user to control the system and any device that is connected in the network. The remote interface will be a web application that is served to the user's computer from the learning hub.

##### **Accessing the Interface**

To load the web application, the user will navigate through a web browser to the address of their learning hub. The hub will then provide the remote interface and prompt the user with a login. The first time the user opens the hub control page they will be prompted to create an account.

##### **Viewing and Controlling Devices**

The primary use of this remote interface will be to observe the state of the system as well as control any connected device. The remote interface must provide access to the recent history of all interactions that have occurred in the system. The interface must provide a mechanism for searching the logs and grouping them based on time and device.

The system must also be able to control the devices that are connected to it. The remote interface must provide the appropriate controls for each device that is connected to the system.

##### **Controlling the Hub**

The interface must graphically provide methods to customize the learning hub's operation. This will include properties related to the system such as network connections, login options and any other hub specific items.

##### **Exiting the Remote**

Once the user is finished with the remote interface, they can log out or simply close the web application. For security reasons, if a user is inactive in their session for more than a set amount of time then they will be logged out automatically.

## Hardware Interfaces

### Learning Hub Interface

To maximize simplicity, the learning hub interface will have a clean and minimal interface. It will provide the user with three control buttons and one reset button. The control buttons will allow the user power off and on the device as well as toggle the state between learning mode, normal mode and standby.

There will also be two external ports on the device. One will be used to power the device from a standard home wall outlet. The other can be a standard Ethernet port and be used to connect to the network.

### 3.2.8 System Data

Aria is a machine learning smart home and must be able to process and analyze the data it collects to produce actions for the end user. In order to accomplish this, data must be collected, organized, and stored in a way which can later be presented to an algorithm as input. This section will outline the different types of information being collected by our system and the importance of this information.

### Devices

Devices are the backbone of any home automation system, as they are the objects being controlled. Different devices such as a light bulb, thermostat, or motion sensor all fill a different role in a home automation system. There needs to be a common way to store information about these devices to enable them to be displayed and controlled through an interactive user interface. Information about how to send messages to devices, what capabilities they have, and about their current state is all important. Once devices are able to be represented, a record of their state changes and factors leading to those state changes must be captured. An example of the structure of a device is shown below.

```

{
  "ZWaveDevice__valueMap":{
    "Bright":null,
    "Color":null,
    "Color Index":null,
    "Dim":null,
    "Level":null
  },
  "address":"44875ab6-ae93-4094-8ff7-5fdf01757f30",
  "deviceType":{
    "attributes":[
      {
        "isControllable":true,
        "name":"Bright",
        "parameters":[
          {
            "dataType":"binary",
            "max":0,
            "min":0,
            "name":"Bright",
            "step":null,
            "value":false
          }
        ]
      }
    ],
    "maker":"Aeotec",
    "name":"ZW098 LED Bulb",
    "protocol":"zwave"
  },
  "name":"ZW098 LED Bulb",
  "version":"4"
}

```

### Device State Changes

Depending on the type of device, a state change can mean many different things. Some devices will have autonomous state changes, such as a motion sensor suddenly detecting motion, while a light bulb will only have a state change if the user explicitly turns it on or off. Our system needs a way to differentiate between events generated by a device automatically and user requests to change a device's state. The system also needs to be able to recognize when an event is directly caused by a user request, and when it is generated by a device. When a state change occurs, the specific information about what value changed on what device must be remembered. Because the Aria system includes a machine learning component, there also needs to be a differentiation between state changes caused by the user and state changes caused by a learned behaviour of the system. An example of a generated event is shown below.

```

{
  type:3,
  data:{
    "attribute":{
      "isControllable":true,
      "name":"volume",
      "parameters":[
        {
          "dataType":"int",
          "max":100,
          "min":0,
          "name":"volume",
          "step":null,
          "value":"56"
        }
      ]
    },
    "device":"Media Room",
    "deviceType":"Sonos PLAY:1",
    "event":"device.event",
    "timestamp":1487799897478
  },
  sender:35434141-4644 -4335-3139 -414530313430,
  receiver:00000000-0000 -0000-0000 -000000000000
}

```

---

## Learning

The user is responsible for training the Aria system to learn any specific desired functionality. They must create the behaviour they want the system to learn, and populate that behaviour with training sessions. There needs to be the capability to then associate any device events and requests with an ongoing training session, and to associate that training session to the correct behaviour. The relationships between user generated state changes, device generated events, and the connection between these and training sessions must be preserved in a such a way that it can be used as input to a machine learning algorithm to estimate intended behaviour.

## Summary

In order to maximize the usefulness of data captured, the events and relationships of the data must be persisted. Persisting these relationships will allow for significantly more meaningful input to the machine learning, and will allow the data to exist across restarts of the system. The ability to persist information in a structured manner and to preserve relationships in the information being stored form the criteria used when evaluating different options for persistence.

### 3.2.9 Data Persistence

There are many different ways to achieve data persistence in a system, each with their own advantages. The data is to be stored on the system's Smart Hub. The Smart Hub run on a Raspberry Pi 3; this choice of hardware will be discussed in a later section. As previously mentioned, the ability to preserve relationships in the data being stored is critical to the success of our system. This functionality, along the hardware constraints of the Raspberry Pi 3, were the driving factors in deciding which data persistence option was best suited for this project. The options that were considered were flat files, a server based Structured Query Language (SQL), NoSQL, and SQLite.

The main advantage to using flat files is that they are quick to set up, and do not take much processing power. However, a flat file has no concept of relations between the information being stored. The level of complexity in the data that is being stored makes being able to represent relationships in the data paramount. There is no data structure enforcement when working with flat files, which makes it difficult to ensure the information is being stored with the required fields. This also implies that the data must be parsed when being read. A specification for the format of data storage would need to be created and followed internally for flat files to be a viable option.

NoSQL is an alternative option to classic SQL solutions. NoSQL is a document based method of data persistence as opposed to the table based methods of SQL, which excels at storing hierarchical relationships. General advantages of NoSQL are that it can be fast, flexible, and has the ability to scale horizontally. This has made it a popular choice for situations where there is big data movement or response time is critical. However, the less rigid nature of NoSQL can present a higher level of complexity, which complicates the database design. The benefits of a NoSQL database are not relevant to this project, and the added complexity makes NoSQL unnecessary and undesirable in this situation. This leads to the last option, which is SQLite.

SQL is a common solution for storing relational data, and has many different concrete implementations. SQL is generally an appropriate choice when dealing with complex queries. Two examples of such implementations are PostgreSQL and MySQL. A common feature of SQL implementations is that they are server based databases. This requires that a separate process is running to support a dedicated server for the database. All requests to the database require a connection to this database server. As mentioned above, the database is being run on a Raspberry Pi, meaning there are a limited amount of computational resources available.

SQLite is a file-based database, which does not require a separate process to run a database server. It essentially acts as a library which can be used across programming languages to access a SQLite file and perform SQL queries and operations. This is the ideal choice for our system, as it fulfills the need for relational data without overburdening the constraints set by our limited hardware.

### 3.2.10 Deployment

### Smart Hub

The central point of control of this smart home system is the smart hub. This hub is the central point of communication for all devices in the smart home system. It houses all of the data storage for events in the system and makes decisions using a smart learning algorithm. The hub will provide a minimal hardware interface for starting the system and changing the system state from training to normal to standby. The smart hub needs to be connected to a internet access point in order for it to serve the web interface to a client's computing device.

### Smart Device

In this diagram, smart device refers to any smart device in the system. This could be a custom built device or a third party device. There will be many of these devices within the system all communicating to the central smart hub.

### Web Client

The web client is the end user's browser and will present a remote interface for controlling the smart hub as well as all devices that are connected to the system. The web interface must be able to render on various industry standard browsers (Chrome, Firefox, IE, Safari).

## 3.2.11 Learning Algorithm

### Introduction

One of the principal goals of the project is allow users to train the system to control their devices without creating explicit rules. The Aria system observes the user's interactions with devices and sensors during *training sessions*. A training session is a short period of time in which the user performs a series of actions that they would like the system to replicate in the future. Actions may include triggering sensors, or controlling the state of an actuator. Each training session is associated with a particular *behaviour* that the user is attempting to teach the system.

From the viewpoint of the Aria system, all user actions and sensor reports during a training session are processed as events; these events are either labelled as user actions or sensor reports. The task of the system is to infer associations between the reported values from sensors and the actions that a user took in response. This process of inferring the relationship between the state of sensors and user actions is referred to as *supervised learning*.

An iterative approach was used for development of the supervised learning component. Starting with a very simple algorithm allowed early experimentation with sensor and device configurations. Building iteratively upon a simple algorithm rather than attempting to use a complex machine learning algorithm or library immediately allows early identification of the challenges that are involved in machine learning. Iterative development also ensures that a basic working algorithm is available if unforeseen difficulties

are found in implementing a more complex solution.

### Strategy Version 1

The first version of the learning strategy considers the list of device and sensor events for a single training session. The simple algorithm proceeds as follows:

1. Find the last user action taken during the training session.
2. Perform that action whenever any event occurs.

Whenever the user completes a training session, the strategy is rebuilt based on the session.

Implementing this simple strategy allowed for development of several building blocks for the machine learning component:

- An entity that observes incoming events and feeds them to the learning strategy.
- An entity that retrieves events from a training session and builds a strategy using the events

The machine learning component makes use of a Strategy Pattern, which allows different implementations of the learning strategy to be interchanged easily.

### Strategy Version 2

The second strategy improved on the previous strategy by looking for all user requests in a training session and associating each one with the event that immediately preceded the request.

### Strategy Version 3

The third and current strategy also looks at all user requests in a training session. Additionally, this strategy uses the state of all sensors at the beginning of the training session to filter out events that did not actually cause a change in the state of the home environment. This strategy triggers a user action based on the first event that indicated a change in the state of the system.

### Future Strategies

The results of testing with the third version of the learning strategy revealed challenges for future improvement. This strategy considers even small changes in the environment to be significant, when in reality they are minor fluctuations in sensor readings. One example found in testing is that the algorithm associated a small change in temperature with user actions, when the desired behaviour was to trigger the action when motion was detected.

Some enhancements that could be made to the algorithm in the future are the discretization of data, and learning behaviours based on multiple training sessions. Discretization of the data could allow the learning component to decide whether a change in a sensor value is significant enough that an action should be triggered. For example, only temperature changes of a certain number of degrees should be considered to be significant changes to the environment.

Future strategies could also consider data from multiple training sessions in order to identify patterns that appear consistently.

## 3.2.12 Technologies

The Aria system is composed of many different technologies that each serve a task specific purpose. This section outlines the details about the technologies chosen and the reasons for them being selected. This section is broken down into the different subsystems of the Aria system.

### Exchange Server

The exchange server is responsible for logging and sending messages throughout the Aria system. It functions as the central communication point for all messages within the Aria system. This server needs to support the main communication protocols that are required for interfacing with several different protocols, including UDP, UPnP, Z-Wave and others. To accommodate this requirement, Python 3 was selected as the primary language.

Python 3 offers support for most of the desired protocols for this system. It can directly interface with C allowing for support of any external library implementations. As for the version decision of Python, choosing version 3 over version 2 allows us to use many of the new features that Python offers. It also means that we are not writing Python using a set of deprecated standards.

### Database

The central exchange server needs to record all events and messages that it receives. This database will be accessed by the exchange server and could be integrated into the exchange process. The database needs to have transaction management but does not need to be a sophisticated database server. SQLite provides all of the required features for this operation and provides the system with a relational data store. Using SQLite means that the system will need SQL to read and write data from the database.

## Quality Control

To maintain the desired level of quality in development, tooling is needed to validate the system. Both static and dynamic techniques for quality control are being used to aid in the development of the smart home system. For static code analysis of the exchange hub, **pyflakes** is being used to stop syntax errors. This tool reads a python file and reports if it conforms to a set of desired constraints.

To check the system's dynamic functionality, the system has sets of integrated unit tests. Python comes with a built in unit testing framework appropriately named **unittest**. This package is being used to develop test stubs and test cases to validate the operations of the exchange. To drive these tests, **nose** is being used. This tool automatically discovers test cases and manages running the test cases in a contained environment. The two tools complement each other and create the basis for the exchange unit testing structure.

## Communication Libraries

In order to interface with different communication protocols, the central exchange is required to use a number of different third party libraries to communicate. These libraries provide direct translation from the exchange's internal message structure to the target devices communication protocol.

### WeMo

The first of the these communication libraries is used to interface to WeMo devices and is titled **netdisco**. This library provides the exchange command with the ability to discover WeMo devices, get device states, as well as send control commands.

## HTTP Gateway

The HTTP Gateway is responsible for serving static web content as well as enabling communication from the web client to the exchange server. The gateway creates a thin wrapper around the internal communication structure of the exchange server and serves it to the web client with a RESTful API. To perform these tasks a simple new web technology, **node.js**, was used. Node is a JavaScript interpreter that provides a massive set of server development tools and libraries.

One of the easiest to use node packages is a web server called **Express**. Express is dynamically configured by coding to its interfaces, which enables rapid development of a web server. This technology has been used for the HTTP gateway to simplify the development.

## Deployment

In order to compile the server into a single executable, **Webpack** is being used. Webpack bundles all of a systems source code into a single file and adds a node.js 'shebang' ( `#!/usr/local/env node` ) to the start. This process allows the simple JavaScript files to be turned into an executable bundle. For the full details of the deployment process, refer to [Appendix I-2](#).

## Package Management

With almost any node.js project there are dependencies. This project is no exception as it uses several packages for runtime, deployment and testing. Fortunately, node.js comes with a default package manager appropriately named **Node Package Manager** (NPM). NPM is the standard for all node.js projects and is consistent across various operating systems.

## Quality Control

To ensure that the code for the hub gateway is adequate and dependable, multiple testing and validation techniques are used. First, the gateway code goes through a static analysis tool called **JSHint** that checks for syntax and lexical errors. This phase quickly indicates where issues may lie in code before it is even tested.

Static testing is quick and often useful, but does not test the execution of the gateway. In order to dynamically test this gateway, the **Mocha** unit testing framework was added. This framework provides a behaviour driven development (BDD) testing language for creating unit tests for the gateway.

## Web Client

The web client is the front end facing user interface that controls the Aria system. The client is responsible for providing observability of the system as well as controllability of the hub and various devices. The web client is intended to be consumed in a user's web browser and therefore must use the language of the web, JavaScript.

## Deployment

Deploying code to different web browsers tends to be a bit tricky, as most browsers deviate on their implementation of the JavaScript language. To ensure that the web client will operate on the lowest common denominator of browsers, a translation layer was used when building the client. This translation tool, called **Babel**, allows JavaScript to be written using the newest version of the ECMAScript specification, `es6`. This allows the JavaScript to still function on browsers that only support the older version `es5`. It does this by transpiling all of the new JavaScript features into the old version equivalent ones.

Once the web client has been converted into browser executable code, it is then bundled into a single web app file using **Webpack**. This is the same tool that is used for the gateway to make it executable. Here the intent is to obfuscate and minimize the size of the web application so that it has a faster load time on client. The full details about the deployment of the web client are outlined in [Appendix I-2](#).

#### Quality Control

Similarly to the gateway, the web client undergoes two phases of testing; static and dynamic. The static phase is exactly the same as the gateway as it is analyzed by JSHint. The dynamic phase slightly differs as the target platform is vastly different from the gateway. In order to dynamically test the remote, a testing library called **Jasmine** was used to write unit tests. This library is similar to Mocha in that it provides a BDD testing grammar for creating unit tests. To run these tests, a test driver called **Karma** was used in conjunction with a daemonized browser called **PhantomJS**. The Karma driver runs the Jasmine tests in the PhantomJS browser to simulate running tests in an end user's browser.

### 3.2.13 Testing

#### Hub Testing

##### Context

The DeviceCommunication, CommunicationServer, and EventLogger components form the core of the system's hub. Each of these components is written in Python, and work together to react to events from devices. They are also responsible for fulfilling requests from the HTTP Server.

Events from connected devices are first received by the DeviceCommunication component, which forwards messages to the CommunicationServer component. CommunicationServer routes messages to the appropriate component, which may be another device HTTPGateway or EventLogger. This section describes the unit testing of each component, as well the method used to test that the components perform correctly together.

##### Unit Testing

The modules that make up each component are unit tested using Python's *unittest* framework. The unit tests are used for regression testing, and are written by the same person who implemented the unit under test.

The *unittest* framework makes use of Python's `decorator` construct to provide an easy way to isolate components for testing. Dependencies such as threading, database, and network libraries can be replaced with a mock objects automatically by declaring a test case with the `@unittest.patch(<dependency-name>)` decorator. These mock objects are used as stubs to provide control the behaviour of the dependencies of a module. For example, mock objects are used to return test data when a module attempts to read data from a network socket.

##### Integration Testing

Interactions between each of the components are triggered by the receipt of messages from smart devices, as well as requests to the REST API. In order to make tests repeatable and to minimize testing time, we chose to test the integration of these components using mock device data. Using mock device test data also allows development of the components to proceed before the implementation of communication with physical devices is complete.

The DeviceCommunication component makes use of an adapter pattern to provide communication with different devices (which may have varying interfaces), through a common interface. This structure provides a simple way to simulate events for testing purposes; an adapter was created which generates events from software source. Automated tests enqueue various messages in the test adapter, which are then propagated through the system as if they came from a physical device.

The choice of SQLite as a database engine makes the system easier to test. SQLite databases are contained in a single file; this makes it inexpensive to tear down and re-create a database which is used for testing. The simplicity of SQLite allows each test case to write to its own instance of the database. The advantage of having one database per test case is that any test failures can be debugged in isolation because the state of the database after a test failure is preserved.

The suite of integration tests also makes use of python's *unittest* framework to create test drivers. Unlike unit tests, the integration test suite does not mock out dependencies such as threads, database, etc. The *unittest* framework is used only to automate the execution of tests, so the behaviour of the components is as close as possible to their actual behaviour when the entire system is running.

## Remote Testing

### Context

The gateway and remote client work closely to provide control and observability to the Aria system. These components are written in JavaScript and need to communicate using a REST API. The gateway is responsible for translating REST communications to the required IPC communicates for all operations. The remote is simply a user interface to interacting with the controls provided by the gateway.

### Unit Testing

The gateway is executed in node.js, a server side environment for JavaScript applications. In order to test the internal behaviours of the gateway, a common BDD testing framework called *mocha* was used. Mocha allows for simple feature based unit tests to be constructed and executed in the node.js environment. Mocha also provides capabilities for spying and mocking internal classes from the gateway code.

The remote client, although written in the same language, runs in very different environments. The web client has to be able to run in a browser. In order to test the functionality of the remote, a unit testing framework called *karma* was used. Karma is a test runner that uses *PhantomJS* to execute its unit tests in a browser environment.

This unit testing library is run against every build of the system and is used for regression testing purposes.

### Integration Testing

In order to isolate the behaviours of the gateway and remote from the exchange server, an interactive integration testing suite was added. This testing suite mocks all communication between the gateway and exchange server in order to control the behaviour of the system. This integration test allows the gateway to run, server the remote client and execute all of the behaviours described by its API. This form of testing has been used to manually test the user interface functionality in a controlled environment.

To start the gateway's integration tests, the gateway executable simply needs to be passed the `--test` flag. This will launch the gateway with all normal parameters but will swap the exchange communication adapter with a mocked adapter.

## 4 Conclusion and Recommendations

---

# 5 Appendix

---

## A Automation Systems

---

### Background

This section contains research on existing home automation systems in order to better understand what technologies currently exist. This research is intended to help understand how a new system could improve on existing technology or if there are particular architecture patterns that are relevant for this system's design. In particular, this research focuses on features that are common between home automation systems and their benefits to the end user.

Since usability is the focus of this system, it is important to investigate the features that a user would expect in a smart home system. It is also important to examine any short comings of existing systems and if these short comings can be addressed.

In order to compare these smart home systems, a set of criteria is required such that they can be evaluated. For this research, the following criteria will be examined: user interaction, device discovery and setup, network configuration, communication protocols, application programming interfaces, third party integrations, and limitations. If there are common protocols across all main automation systems then they should be considered for this system. Industry standard protocols may be discovered by reviewing these existing systems. If there is a special focus on the ease of use then this system should consider the efforts that other systems have taken. The network configuration of a system will govern its performance, power consumption and allowable number of connections. This research will investigate how these systems organize their network topologies to satisfy these quality attributes. In order to control these devices we require that the following; a way to view all connected devices, a way to get notifications when a device in the system changes states, a way to change the state of a device. Finally, if there are accepted standards of third party integrations then this system should consider them in its design to maximize overall interoperability.

### A-1 Insteon

#### Description

Insteon is a home automation system that allows smart devices to connect over a home area network with a focus on ease of use. Insteon allows you to monitor and control all of the devices within the system. All devices in connect through a central Insteon smart hub which is then controlled by the user through a app on the user's mobile device. Controlling devices can also be automated using manually configured schedules, IFTTT or through the use of **scenes**.

A scene allows a user to configure device behaviours based on grouping of devices in their home. The devices are grouped into rooms which can represent the physical rooms of the home. The user can then create a configuration for a specific date, time or environmental condition. Insteon then monitors the state of the home for these conditions, when they are met then it recreates the user's configuration <sup>13</sup>.

#### Technical Overview

##### User Interaction

In order to communicate with devices, Insteon provides a central hub that acts as the main point of control for the smart home. The user will be required to pair any devices that are added to the smart home with the hub so that it can be controlled <sup>14</sup>. Once the devices have been paired with the hub, the user can control the devices remotely using the Insteon smart phone app. The Insteon app gives the user the ability to monitor and control all of the devices in their smart home, automate tasks with schedules, build scene configurations, and receive alerts about devices in their home <sup>15</sup>.

##### Device Discovery and Setup

Initial setup of the smart home requires the Insteon hub to be installed in the home and connected to a network <sup>16</sup>. Once the hub has been connected to a network it must be paired with the user's smart phone app so that the user can access the Insteon user interface.

Adding a new device is done through the Insteon app. A new device is first plugged in and turned on. The device then locates the user's mobile app on the network and is ready to be connected. Using the app the user selects the new device and enters the device identifier. Once the identifier is entered the device is able to be configured and added to the Insteon network <sup>17</sup>.

##### Network Configuration

Insteon uses a central hub to communicate between the devices and the users app <sup>18</sup>. The Insteon hub is used for all device communications and control. Devices connect and send all event information to the central hub for processing and storage. The user can then interact with the devices in their network through the Insteon smart phone app.

Insteon uses a peer-to-peer network to connect the devices <sup>19</sup>. All of Insteon's devices can act as a controller to send messages, a repeater to forward messages or a responder to receive messages.

### Supported Communication Protocols

Insteon uses a proprietary messaging protocol to send messages between devices and a smart hub. The Insteon messaging protocol uses message repeating to send messages across a peer-to-peer network of devices. This messaging protocol is outlined in a detailed [white paper](#) that describes the network protocol as well as the messaging protocol <sup>20</sup>.

Additionally, Insteon has introduced power lines as a medium for device communication. Insteon uses the circuits that power a home as a secondary mechanism for communicating data between devices and the smart hub <sup>21</sup>. This power line communication as well as the wireless Insteon protocol are explored in more details in the research of [communication protocols](#).

Insteon also integrates with a number of third party devices and controllers. These third party devices can be added to the network and be controlled through the Insteon smart hub. The hub's devices can also be controlled through the integrations of these third party devices <sup>22</sup>.

### Application Programming Interfaces

Insteon provides a complete REST API for querying the properties of their hub. The REST API allows a client to query properties about the hub, the connected devices, any connected cameras, contacts, scenes, rooms and more. The API also provides endpoints for setting data values in devices and configuring properties of users <sup>23</sup>.

The REST documentation does state that there are some limitations in the design of the protocol. It states that the REST API does not provide full support for configuring devices and scenes and states that the Insteon app is still required for complete access <sup>24</sup>.

### Third Party Integration

Insteon produces its own devices for most of its smart home purposes <sup>25</sup>. On top of these basic devices, Insteon has created integrations with a number of third party smart technology vendors. These vendors include: Nest, Logitech, Amazon Echo, Stringify, Apple HomeKit, Cortana, First Alert, Sonos, and MiLocks <sup>26</sup>. This exceptional list of partners demonstrates that the Insteon API is flexible enough to support many existing industry technologies. This may indicate that their platform is generic enough to support all smart device requirements. The framework developed by Insteon would be a valuable area of study for this project's design.

### Limitations

As stated in the API section of this analysts, in order to properly configure all devices and scenes in the Insteon system, the Insteon app is required. This limitation impedes on the user experience of the system and would hurt the overall usability.

### Summary

Insteon is a mainly proprietary home automation system that focuses on user interaction through the use of a smart phone application. The system uses a central hub to communicate to all of its devices through a proprietary communication protocol. Users are given the ability to monitor, control, schedule and configure the devices in their smart home using the Insteon app.

Insteon has a wide variety of third party integrations but offers only an incomplete API for controlling their own devices. This smart home does not allow third party code to run on their hub and requires that their app be installed on a user's smart phone in order to properly control their devices. These extensibility issues make the Insteon platform a closed, commercialized system that would not be able to support additional development of a non-partner organization.

## A-2 Wink

### Description

Wink is a smart home automation system that prides itself on simplicity and user experience. The Wink system provides standard smart home features such as monitoring and controlling of devices, but also offers more advanced features such as energy consumption monitoring <sup>27</sup>. Wink uses a central hub architecture, where all devices in the network communicate to a single "smart" hub. Additionally, Wink provides a smart phone app for users to interact with the system <sup>28</sup>.

### Technical Overview

## User Interaction

User interaction in the Wink system begins with its smart hub. This hub is the central point of communication for devices in the smart home. Once devices have been added to the smart hub, the user can control the hub and all of its devices with the Wink smart phone app <sup>29</sup>. The app provides a clean, simple interface for monitoring and controlling all devices on the smart home network.

Additionally to the app, the Wink platform offers a custom built touch screen remote control. The remote controller allows the user to use all of the features of the smart home without the use of a smart phone app <sup>30</sup>.

In order to offer a better user experience, Wink provides a "shortcuts" feature where a user is given the ability to control multiple devices with one command <sup>31</sup>. This feature allows users to setup and configure related devices to perform desired tasks. When the user invokes the shortcut, the system will apply all of the user's initial configurations <sup>32</sup>. The shortcut feature certainly adds value to the Wink system but does require manual configuration to setup the desired shortcut.

## Device Discovery and Setup

Wink does not offer any of its own smart home devices. Instead, it utilizes the vast market of existing devices by supporting various different third party integrations. Supporting many different manufacturers means that there are two different ways for devices to connect to the Wink Hub. Pressing a button on the Wink Hub broadcasts a pairing signal across the network <sup>33</sup>. Any new device that receives this signal will then appear on the network, and can be viewed from the Wink app. The user then selects the new device and enters the device identifier (located on the physical device) to add it to the automation system.

If the new device requires a setup through a third party app then the new device must be added to the home network using the app provided by the manufacturer. Once it has been added through the manufacturers app, it will be visible using the Wink app. It can be added to the automation system from here using the Wink app <sup>34</sup>.

## Network Configuration

Wink's central hub provides several communication protocols, all of which are wireless. In order to communicate to the hub, the user must setup a WiFi connection. This can be done initially by connecting a smart phone to the hub's internal WiFi network and then using the smart phone app <sup>35</sup>. Once the hub has been setup to connect to a local area WiFi network, the smart phone app can be used to control the devices connected to the hub. If the WiFi network contains an internet link then the smart phone app can be used outside of the home to monitor and control the home <sup>36</sup>.

## Supported Communication Protocol

The Wink hub offers connections to multiple different communication protocols in order to maximize its third party integrations. As a minimum, the hub must be connected to WiFi so that the hub can connect to the Wink smart phone app. Beyond that, the Wink hub offers connections for Bluetooth, Z-Wave, ZigBee, Lutron's Caseta, and Kidde protocols <sup>37</sup>.

## Application Programming Interfaces

Wink provides a RESTful service through the Wink hub and a secondary partner PubNub. This API can be accessed through the Wink web server for third party integrations. The service offers basic smart home features including monitoring and controlling devices. Wink also offers controls for creating groups of devices that can be used for shortcuts in their service <sup>38</sup>.

## Third Party Integrations

Since Wink does not make any of their own smart devices, they rely heavily on third party integrations. The table below lists all of the organizations that have partnered with Wink to offer devices that are compatible with the Wink system.

Nest	Philips	GE	Leviton	Rheem
Honeywell	TCP	Kidde	Kwiset	Lutron
Rachio	Bali	Amazon	Andersen	Canary
Carrier	Chamberlain	Commercial Electric	Cree	Dropcam
Ecobee	Emerson	GoControl	Hampton Bay	IHome
Leaksmart	Osram			

## Summary

Providing support for the most popular communication protocols allows Wink to connect with almost any device a user can purchase, making them an attractive option to consumers. Their central hub design allows them to be compatible with many third party devices as well as offer the user a simple setup experience. Finally, Wink offers a simple, elegant user interface through their smart phone app or smart remote controller. These features make Wink an appealing smart home automation system for a non-technical user.

### A-3 SmartThings

#### Description

SmartThings is Samsung's home automation system. Similar to Wink, they provide their own app allowing a user to control devices using scheduling or IFTTT.

#### Technical Overview

##### Communication Protocols

SmartThings supports devices that communicate using the Z-Wave, ZigBee, or WiFi communication protocols

##### Device Discovery and Setup

Adding a new device is done through the app. A user will click "find device", prompting the hub to search for any new Z-Wave, ZigBee, or WiFi devices. When the device is found the user adds it to a room and names the device.

##### Network

SmartThings uses a central Hub to connect all of the smart devices. The SmartThings app talks with the SmartThings Cloud which talks to the Hub which then controls the devices.

##### API

SmartThings provides a Groovy API to create SmartApps that allow control of devices.

Feature	Supported
List all devices	Y
Receive update on device state change	Y
Modify device state	Y

##### Limitations

Requires a SmartThings hub and connection to the SmartThings cloud.

##### Third Party Integrations

2Gig	Aeon Labs	Amazon	Belkin	Bose
Cree	ecobee	Ecolink	EcoNet Controls	Enerwave
Everspring	Fibaro	Fidure	First Alert	FortrezZ
GE	Google	Honeywell	iHome	Keen Home
Kwikset	Leak Intelligence	Leviton	LiFi Labs	Linear
Netgear	OSO Technologies	OSRAM LIGHTIFY	Philips Hue	Remotec Technology
Samsung	Samsung SmartThings	Schlage	Sengled	Skybell
Spruce	Yale	Zen		

##### Summary

The Samsung home automation system provides a reasonable level of support for different communication protocols, giving it a healthy amount of third party support. This is something that we will be striving for in our project. The dependency on the connection to a cloud service is something that we would like to avoid for our project.

## A-4 Apple HomeKit

### Description

Apple HomeKit allows users to control their smart devices using their iPad or iPhone. Apple HomeKit does not require any central hub to control the devices, but does require there to be an Apple device connected to the network at all times. If a user wants to control devices with an iPhone while not at home, the devices must be connected to an Apple product that is connected to the network, such as an iPad or Apple TV.

### Technical Overview

The smart devices are able to be scheduled and controlled in groups from the app.

### Communication Protocol

Apple HomeKit uses WiFi as the only communication protocol.

### Device Discovery and Setup

Adding new devices is done through the app. Once a device is connected to the network it can be added to the home through Apple's app, some devices require some configuration in their manufacturers apps.

### Network

HomeKit uses the home's WiFi network to connect devices and all devices on the network are able to communicate with one another.

### API

Feature	Supported
List all devices	Y
Receive update on device state change	Y
Modify device state	Y

### Summary

There are a few aspects of the Apple HomeKit that are not ideal for incorporation into our project. First, it is Apple exclusive, which goes against the goal of having many third party support options. The lack of a central hub also makes it difficult to having support for many different types of devices. The level of communication between devices that is offered by the Apple solution is a desirable feature, but will be difficult to achieve while maintaining diverse third party support.

## A-5 Summary

A common theme among existing home automation systems is that systems with a large amount of third party support rely on a central communication hub. Having a hub allows components from different manufacturers to communicate to each other through the hub. A challenge that supporting a large number of devices presents is how to discover new devices into a system, which can be dealt with in several different ways such as manual button pressing or app configuration.

Looking at these systems also presented several communication protocols to investigate, including Z-wave, Zigbee, Insteon and WiFi. Along side these are devices from many different manufacturers which operate using these communication protocols. Deciding on a communication protocol and subsequent device manufacturers to support is an important part of our design for our home automation system.

## B Computing Devices

---

## Background

A computing device is any electronic device that can be used to process data and send it over a smart home network. Computing devices include computers, micro-controllers and other embedded devices. Computing devices that are being examined all offer control of external hardware interfaces. This report examines computing devices that can be used for prototyping embedded control of sensors and actuators.

## Relation to System

Computing devices will be used for many aspects of the smart home system. A computing device will be used for the central smart hub as well as for various other devices in the system. Different devices will be more suitable to some tasks than others. This report compares a number of these computing options with a focus on the areas of need within the system.

## B-1 Arduino Uno

### Description

The Arduino Uno is a small starter microcontroller that is intended for hobby projects and newcomers to embedded programming. The Uno is intended for rapid prototyping of small circuits and small embedded systems.

### Technical Overview

The Uno is a microcontroller that uses the Arduino boot loader software for launching the system and executing code. The Uno is fully compatible with the Arduino SDK that provides simple access to all pins and controls on the board. The Uno comes with a 8-bit ATmega328P processor running at 16 MHz. The system comes with 32 kB of on board flash memory as well as 2 kB of SRAM and 1 kB of EEPROM. The system boot loader occupies 0.5 kB of the flash memory capacity <sup>39</sup>.

The Uno comes with 14 digital pins, 6 of which can be programmed to use pulse width modulation. Included in the microcontroller are 6 analog to digital input pins. The board has a operating voltage of 5 V and will accept between 7-12 V for input pins. The maximum voltage range of the input pins are 6-20 V <sup>40</sup>.

The Uno is a medium sized microcontroller that is 68.6 mm long and 53.4 mm wide. It has a total weight of approximately 25 g. The Uno also includes an integrated USB-Mini port used for serial communication and as a power source. The board includes a 5 V DC power input for running the board continually <sup>41</sup>.

### Summary

The Arduino Uno offers fast and simple prototyping options for quickly building embedded circuits. This board is very useful for rapidly testing but would not be practical in a mass production system. For the smart learning system, this board would be optimal for experimentation and quick deployment.

## B-2 Arduino 101

### Description

The Arduino 101 is a more sophisticated board that uses the Intel Curie processor for computing. This board leverages the Real-Time Operating System (RTOS) developed by Intel for running the board.

### Technical Overview

The Arduino 101 is the most feature rich board that Arduino is offers. It comes with a full Real-Time Operating System (RTOS) that is powered by the Intel Curie. The processor is a 32-bit, 8 MHz or 16 MHz backed by 196 kB of flash memory. The RTOS is a light weight OS that only occupies 2 kB of memory to provide managed, concurrent applications <sup>42</sup>.

The 101 comes with a number of additional features above other microcontrollers in the Arduino family. Beyond the standard USB-Mini serial connection, the 101 offers a 6 axis gyroscope accelerometer and integrated Bluetooth. The 101 also provides a 5 V DC power input for deployment use <sup>43</sup>.

The 101 offers many of the same prototyping capabilities as the Uno with 14 digital pins, 4 of which provide pulse with modulation. The 101 also exposes 6 analog to digital pins <sup>44</sup>.

### Summary

The 101 is a much more feature rich board than the Uno, however the added features are not applicable to this project. The 101 also has a much higher price point per unit than the Uno with no real added value. This makes the Uno a more appealing candidate for rapid prototyping and simple circuit design.

### **B-3 Arduino Pro**

#### **Description**

The Arduino Pro is a slim, no frills version of the Arduino Uno. This board requires more technical knowledge than the Uno or the 101. All pins exposed on the Pro require soldering to make a connection. The Pro is intended for replication of a complex circuit design with requirements for a wide range of input and output ports.

#### **Technical Overview**

The Pro is an embedded system that leverages the Arduino boot loader and a 32-bit ATmega328 processor. The Pro has two operating speeds; 8 MHz or 16 MHz. This device has an operating voltage of 5 V but has a lower power alternative that runs at 3.3 V. The Pro has the same limited memory as the Uno with only 32 kB of flash memory, 0.5 kB of which is occupied by the boot loader <sup>45</sup>.

The Pro offers the same pin configuration as the 101 with 14 digital pins, 4 of which can be pulse with modulation, and 6 analog pins. The Pro also provides some more advanced I/O options with a universal asynchronous receiver / transmitter (UART), serial peripheral interface (SPI) bus, and an inter-integrated circuit (I2C) connection <sup>46</sup>.

#### **Evaluation**

The Pro has many advanced features but offers little in the way of rapid prototyping. The Pro is intended for a more advanced audience than what is required for this project and is likely not a good candidate for practical applications. However, if this system was to be replicated or redistributed, the Pro would be useful for building a final product for an unmodifiable system.

### **B-4 Arduino Micro**

#### **Description**

The Arduino Micro is the smallest microcontroller of the Arduino family. The Micro also provides the most external ports of any Arduino making it suitable for large circuits.

#### **Technical Overview**

The Micro provides high performance embedded computing with a 8-bit, 16 MHz ATmega32U4 processor. The Micro also comes standard with the Arduino bootloader and a standard 32 kB of flash memory. The Micro has a operating voltage of 5 V and comes with a standard DC power input <sup>47</sup>.

The Micro has 20 exposed digital pins, 7 of which can be pulse width modulation. These extra pins make the Micro very suitable for large complex circuits that require many inputs or outputs. The Micro also has 12 analog to digital pins. The Micro does lack in special features. It only offers serial communication over a standard USB-Micro port. There are other special features with this device <sup>48</sup>.

Appropriately, the Micro is the smallest and lightest microcontroller in the Arduino family. It is only 48 mm long and 18 mm wide. The Micro also only has a weight of roughly 13 g <sup>49</sup>.

#### **Summary**

This Arduino would be perfectly suited to a mass production environment where size and weight were valuable resources. If the learning home automation system was to be commercially produced, this could be a very valuable microcontroller. This microcontroller could be used for this system, but would take more effort for prototyping and would likely not be a suitable fit.

### **B-5 Comparison of Arduinos**

#### **Operation Criteria**

Criteria	Arduino Uno	Arduino 101	Arduino Pro	Arduino Micro
Operating System	None	RTOS	None	None
Processor Size	8-bit	32-bit	32-bit	8-bit
Processor Family	ATmega	Intel	ATmega	ATmega
Operating Voltage	5 V	3.3 V - 5 V	3.3 V - 5 V	5 V
Input Voltage	7 - 12 V	7 - 12 V	7 - 12 V	7-12 V
Clock Speed	16 MHz	8 MHz - 16 MHz	8 MHz - 16 MHz	16 MHz
Digital Pins	14	14	14	20
Pulse with Modulation Pins	6	4	4	7
Analog Input Pins	6	6	6	12
DC Current per Pin	20 mA	20 mA	40 mA	20 mA
Flash Memory	32 kB	196 kB	32 kB	32 kB
System Size	0.5 kB	2 kB	2 kB	4 kB

## Features

Feature	Arduino Uno	Arduino 101	Arduino Pro	Arduino Micro
USB	USB-Mini	USB-Mini	USB-Micro	USB-Micro
Accelerometer	No	6-Axis Gyro	No	No
Bluetooth	No	Yes	No	No
UART	No	No	Yes	No
SPI Bus	No	No	Yes	No
I2C	No	No	Yes	No

## Physical Characteristics

Dimension	Arduino Uno	Arduino 101	Arduino Pro	Arduino Micro
Length	68.6 mm	68.6 mm	52.1 mm	48 mm
Width	53.4 mm	53.4 mm	53.3 mm	18 mm
Weight	25 g	34 g	N/A	13 g

## B-6 Raspberry Pi Zero

### Description

The Raspberry Pi Zero is a minimal computer board that offers a full computing platform in a compact form for embedded computing. The Zero is the smallest board in the Raspberry Pi family and is ideal for medium to heavy computation with minimal footprint. The Raspberry Pi Zero is one of the only Raspberry Pi boards that competes for a real embedded computing experience.

### Technical Overview

The Raspberry Pi Zero has the smallest surface area of any of the Pi's, measuring in at only 65mm long by 30mm wide. To make the board as small as possible, many of the standard Raspberry Pi features were removed. This means that the Zero has no on-board WiFi, Bluetooth or even Ethernet. Despite these losses, the board is still equip with a 32-bit 1GHz Broadcom BCM283 processor backed by 512MB of flash storage <sup>50</sup>.

The Zero provides a lot of room for flexibility with 40 available GPIO pins. The combination of the Zero's computing power and general IO makes it ideal for small spaces that need a lot of power <sup>51</sup>.

### Summary

The Zero could be useful for programming devices in the system; however, while the Zero does offer a smaller physical footprint and more GPIO pins than the Arduino Uno, it does require more power to maintain operation. This extra power consumption does come with more performance which may be useful but likely unnecessary for the smart learning system.

## B-7 Raspberry Pi 1 Model A+

### Description

The Raspberry Pi 1 Model A+ is the original Raspberry Pi with some performance improvements. This device is a computing board that provides desktop equivalent computing power in only a few square inches of space. The Pi 1 is the first candidate being considered for the role of the smart home learning hub.

### Technical Overview

The Pi 1 is the base Raspberry Pi that is powered by a 32-bit 700MHz Arm processor and 256MB of DDR2 RAM. The Pi 1 comes with a standard HDMI output for visual output. The board also comes with a standard Ethernet port, and a single USB port for serial communication. The Pi 1 does also offer 40 GPIO pins for more embedded purposes <sup>52</sup>.

### Summary

The Raspberry Pi 1 is a good candidate for the central hub as it uses low power and provides adequate computing performance.

## B-8 Raspberry Pi 2 Model B

### Description

The Raspberry Pi 2 Model B is the second generation of Raspberry Pi designs. The Pi 2 uses the same design as the Pi 1 with all the same features and more performance.

### Technical Overview

The Pi 2 is very similar to the Pi 1 but provides a slight faster 32-bit 900 MHz Arm processor. The Pi 2 has significantly more RAM than the Pi 1 with 1GB of DDR2 <sup>53</sup>. The Pi 2 comes with a standard HDMI video output for monitoring it from a screen. It also is equipped with an Ethernet port and 4 USB ports. The Pi 2 also provides the same 40 GPIO pin configuration as the Pi 1 <sup>54</sup>.

### Summary

The Pi 2 outperforms the Pi 1 in all areas and is likely a better candidate for the smart hub. It uses the same amount of power but provides far more computing performance.

## B-9 Raspberry Pi 3 Model B

### Description

The Raspberry Pi 3 Model B is the most advanced Raspberry Pi available. The Pi 3 is a computer board that uses a very similar design to the other Pi Models. The Pi 3 offers more computing performance than all of its predecessors and is a very suitable candidate for the smart hub.

### Technical Overview

The Raspberry Pi 3 offers massive embedded performance with a 1.2 GHz 64-bit Quad-core Arm processor <sup>55</sup>. Similar to the Pi 2, the Pi 3 also comes with 1GB of RAM. As with all other Pi models, the Pi 3 provides a 40 GPIO pin configuration for external devices. <sup>56</sup>

The Pi 3 also comes with a number of standard options that set it apart from all other Pi models. It comes with integrated WiFi, Ethernet and Bluetooth communication interfaces <sup>57</sup>. It has 4 standard USB ports and an HDMI output for visual feedback <sup>58</sup>.

## Summary

The Raspberry Pi 3 is the most advanced Raspberry Pi board available. Its extra computing power would be a good asset for heavy computation making this an ideal candidate for the central smart hub. The Pi 3 comes with many standard features including WiFi and Bluetooth communication which will make external interfacing simple with minimal investment.

## B-10 Comparison of Raspberry Pi

### Operation Criteria

Criteria	Raspberry Pi Zero	Raspberry Pi 1	Raspberry Pi 2	Raspberry Pi 3
Operating System	Raspbian	Raspbian	Raspbian	Raspbian
Processor Size	32-bit	32-bit	32-bit	64-bit
Processor Family	Broadcom	Arm	Arm	Arm
Operating Voltage	5 V	5 V	5 V	5 V
Input Voltage	3.3 V	3.3 V	3.3 V	3.3 V
Clock Speed	1 GHz	700 MHz	900 MHz	1.2 GHz
Digital Pins	40	40	40	40
Pulse with Modulation Pins	N/A	N/A	N/A	N/A
Analog Input Pins	N/A	N/A	N/A	N/A
DC Current per Pin	50 mA	50 mA	50 mA	50 mA
Flash Memory	512 MB	256 MB	1 GB	1 GB
System Size	1.6 GB	1.6 GB	1.6 GB	1.6 GB

### Features

Feature	Raspberry Pi Zero	Raspberry Pi 1	Raspberry Pi 2	Raspberry Pi 3
USB	USB-Micro	1	4	4
HDMI	Mini-HDMI	Yes	Yes	Yes
Bluetooth	No	No	No	Yes
WiFi	No	No	No	Yes
Audio	No	3.5 mm Jack	3.5 mm Jack	3.5 mm Jack
Ethernet	No	Yes	Yes	Yes
Camera Interface	No	Yes	Yes	Yes
Display Interface	No	Yes	Yes	Yes
Micro SD	Yes	Yes	Yes	Yes

### Physical Characteristics

Dimension	Raspberry Pi Zero	Raspberry Pi 1	Raspberry Pi 2	Raspberry Pi 3
Length	65 mm	85 mm	85 mm	85 mm
Width	30 mm	56 mm	56 mm	56 mm

## B-11 BeagleBone

### Description

The BeagleBone is another computing board that is on the edge of embedded computing. The BeagleBone is a small, feature rich, Linux system for concurrent, real-time embedded programming. This board could be used for the learning hub or even a small device that requires more computation power than a microcontroller can offer.

### Technical Overview

The standard BeagleBone is very comparable to the Raspberry Pi 2 in features and performance. It is driven by a 32-bit 700MHz Arm processor with 256MB of flash memory. This computing board offers 2 USB ports and a standard Ethernet port for external communication <sup>59</sup>.

The BeagleBone stands out from the Raspberry Pi with its general pin configurations, as it offers 60 GPIO pins <sup>60</sup>. This makes the BeagleBone more suitable for embedded computing than the Raspberry Pi models. The BeagleBone is a Linux compatible board that comes with the Angstrom distribution <sup>61</sup>.

### Summary

The BeagleBone has a number of useful features for embedded computing but does not provide as much computation performance as the Raspberry Pi 3. The BeagleBone may be suitable for other devices in the system that require more computational power than what a traditional microcontroller can provide.

## B-12 BeagleBone Black

### Description

The BeagleBone Black is a more advanced version of the standard BeagleBone. It provides more features and is a higher performance system than the standard board. The BeagleBone Black is most comparable to the Raspberry Pi 3 board in terms of performance and features. The Black model still offers all of the major BeagleBone embedded features making it a good candidate for both the learning hub and other computing devices

### Technical Overview

The BeagleBone Black is driven by a 32-bit 1GHz Arm processor and is backed by 512MB of RAM. It also comes with more standard communication options than its predecessor including WiFi and Bluetooth. The Black model comes standard with 2 USB connections for serial communication and an HDMI interface for video feedback <sup>62</sup>.

The Black Model uses the same pin configuration as the basic BeagleBone with a few extra specialty pins. It provides 68 GPIO pins with an additional UART connection <sup>63</sup>.

### Summary

The BeagleBone Black does have many powerful features but cannot compete with the Raspberry Pi 3 for the learning hub roll. The Black model may be useful for embedded devices that require additional computation but since it requires more power than the standard BeagleBone with minimal gain it may not be feasible.

## B-13 BeagleBone Green

### Description

The BeagleBone Green is the best embedded option of the BeagleBone family. It is a computing board that runs a full operating system but has the most available circuit controlling pins. It is an ideal candidate for both the learning hub and smart devices.

### Technical Overview

The BeagleBone Green model is powered by the same 32-bit 1GHz processor as the Black model. It also has the same 512MB of RAM available. Almost all of the core features of the Green model are the same as the Black model. The Green model stands out with its 4 additional pulse width modulation pins and 3 additional analog pins. In addition to a UART connection, the Green model provides an I2C connection <sup>64</sup>.

### Summary

The Green model shares many of the same features as the Black and is therefore not an adequate alternative for the Raspberry Pi 3 and the learning hub. However, the Green does require less energy than the Black model and is possibly a better candidate for embedded devices.

## B-14 Comparison of BeagleBone

### Operation Criteria

Criteria	BeagleBone	BeagleBone Black	BeagleBone Green
Operating System	Angstrom	Debian	Debian
Processor Size	32-bit	32-bit	32-bit
Processor Family	ARM	ARM	ARM
Operating Voltage	5 V	5 V	5 V
Input Voltage	1.8 V	1.8 V	1.8 V
Clock Speed	700 MHz	1 GHz	1 GHz
Digital Pins	60	68	65
Pulse with Modulation Pins	4	4	8
Analog Input Pins	4	4	7
Flash Memory	256 MB	512 MB	512 MB
System Size	1.8 GB	2.2 GB	2.2 GB

### Features

Feature	BeagleBone	BeagleBone Black	BeagleBone Green
USB	2	2	2
HDMI	No	Yes	No
Bluetooth	No	Yes	Yes
WiFi	No	Yes	Yes
Ethernet	Yes	Yes	Yes
UART	No	Yes	Yes
I2C	No	No	Yes
Micro SD	Yes	Yes	Yes

### Physical Characteristics

Dimension	BeagleBone	BeagleBone Black	BeagleBone Green
Length	86 mm	86 mm	86 mm
Width	54 mm	54 mm	54 mm

## B-15 Summary of Devices

### Embedded Devices

There will be a number of applications for embedded devices in the smart home system. There may be various computing devices that are suitable for different tasks depending on the requirements. However, for the general needs of the embedded computing in this system, the Arduino Uno will likely be the most suitable candidate.

The Uno provides a rapid prototyping environment with support for a wide array of custom devices. It has sufficient computing power with minimal power consumption for the requirements of the general devices that have been identified in the system scenarios.

As an added benefit, the Arduino community offers many high quality tutorials, examples and documentation of system usage. The extensive support offered by the community is a major advantage over the other systems and will be a major asset for developing on this device.

## **Learning Hub**

The learning hub will require a significant amount of computational performance to make decisions about home environment. For this component, full computer boards were considered as they provide more performance than the available microcontrollers. After a close examination of a number of computing devices it was determined that the Raspberry Pi 3 Model B is the most suitable option for this roll in the system.

Since this device is heavily reliant on performance, the decision was reduced to 2 candidates, the Raspberry Pi 3 and the BeagleBone Black. They both offer considerable performance but the Pi 3 offers more processing cores with a higher clock speed, larger registers and more RAM. This makes the decision simple, the Pi 3 is the better candidate.

# **C Communication Protocols**

---

## **Background**

There are many different ways to connect devices across a network. A familiar example is WiFi, but other protocols are available that specialize in different aspects of wireless communication. The goal of this section is to investigate the strengths and weaknesses of different communication protocols, and evaluate them against each other according to the requirements of the project.

## **Selection Criteria**

The criteria used for evaluating communication protocols are based on the non-functional requirements identified for the system. The key requirements pertaining to communication protocols are ease of integration with devices, battery life of devices, range, interoperability, data transfer rate, number of concurrent connections. Another important aspect of a communication protocol that will be evaluated is what frequency it operates on.

## **C-1 ZigBee**

### **Description**

The goal of the ZigBee protocol is to provide an efficient way to transfer small amounts of data over a limited distance. Relative to WiFi, the decreased data transmission rate and range of ZigBee allows compatible devices to consume less power allowing for increased battery life and energy efficiency. ZigBee shields are available for many popular embedded communication devices, allowing them to communicate with ZigBee compatible smart devices. Many companies offer smart devices which are compatible with the ZigBee protocol, such as lights and light switches.

### **Technical Overview**

ZigBee uses a mesh networking topology, as opposed to the star topology used by WiFi <sup>65</sup>. A mesh topology means that every node in the network is connected. Each node transmits its own information, as well as assisting in relaying information received from other nodes. Having every node connected allows for data to be transmitted between nodes simultaneously, and increases network stability on not relying on one central node. This increase in stability comes at the cost of having potentially many redundant connections in the network. ZigBee devices use the mesh topology to send messages using message routing. This means that if the endpoint device is out of range of the initial device. Intermediate devices will relay the message through the mesh until it reaches its endpoint.

ZigBee operates within three possible frequency bands: 868-870 MHz, 902-928 MHz, and 2.4-2.4835 GHz <sup>66</sup>. The lowest band only has one available channel, the middle band has ten available channels, and the highest band has 16 available channels. The respective data transfer rates are 20 kbps, 40 kbps, and 250 kbps. It should be noted that devices on different frequency bands cannot communicate with each other, and generally only devices using the 2.4 GHz range are commercially available.

The low power consumption of ZigBee devices when compared to WiFi leads to better energy efficiency and a longer battery life <sup>67</sup>. Theoretically, up to 256 devices can be connected to one network. However, in practice, the system performance tends to degrade at around thirty devices <sup>68</sup>.

One of the major drawbacks of ZigBee is that for it to be effective, it must operate in the 2.4 GHz frequency band. This would not be an issue, except for the fact that this is the same frequency band as older versions of WiFi. This can cause interference between the two networks, resulting in packet loss for both networks. The lost packets have to be retransmitted until they are received by the intended endpoint, causing lag in both networks. ZigBee packets suffer more from this interference in practice, with the level of interference rising as the number of nodes and the amount of traffic rises. Fortunately, newer WiFi networks operate on the 5 GHz channel which would eliminate this interference <sup>69</sup>.

A second potential drawback of ZigBee is the historical lack of official standards for application-level protocols for ZigBee devices. While ZigBee devices all communicate using the same physical layer protocol, each device may use a different high-level protocol for device control. The result of this lack of standardization is that different companies have their own protocols for ZigBee device communication, so devices from different companies cannot be assumed to be compatible. The limited interoperability has been somewhat fixed with the introduction of the ZigBee Alliance, but could present some legacy issues <sup>70</sup>.

## C-2 Z-Wave

### Description

Z-Wave is a very similar option to ZigBee, except it has a public application level specification. Having this application level specification makes it easy to program with, eliminating the potential for interoperability issues between devices. This is a major component which ZigBee lacks. It is another low power and low data transfer rate communication protocol, designed specifically for use in an Internet of Things project. The Z-Wave protocol is proprietary to Sigma Designs, but a public specification was released, making it easily accessible <sup>71</sup>.

### Technical Overview

One area where Z-Wave differs from ZigBee is the frequency range of operation. It operates at 908.42 MHz instead of at 2.4 GHz, which avoids the issue of conflicting with WiFi signals <sup>72</sup>. In terms of device limits, it is very similar, being able to handle between 30 and 40 devices before issues start to occur <sup>73</sup>. Z-Wave is similar to ZigBee in terms of device range and power consumption. Z-Wave has an even lower data transfer rate than ZigBee at 40 kbits/sec <sup>74</sup>.

## C-3 Insteon

### Description

Insteon is substantially different from the ZigBee and Z-Wave protocols. It is not a public specification of any kind. It is a fully closed off system that only operates within itself. Insteon used both a wireless frequency and powerline to communicate, providing more stability than most other home automation communication protocols. The technical information below is directly from the Insteon whitepaper <sup>75</sup>.

### Technical Overview

Insteon uses a similar mesh topology to the above protocols, but it is not limited to radio frequencies. It utilizes a dual-mesh system to increase overall stability. The dual-mesh system is a combination of radio frequencies at 915 MHz (in the US), and powerline layer operating at 131.65 KHz. Powerline communication is a technology that uses a home's electrical wiring to transfer data.

When the radio frequencies encounter interference, the powerline layer makes sure the message gets broadcasted to the appropriate destination. Insteon also uses a different message delivery system compared to ZigBee and Z-Wave. Instead of sending a message from one device and routing it through other devices, it takes advantage of simulcasting. This is the process of having

multiple devices broadcasting the same message, so the intended recipient gets the message faster and more reliably. This method is not feasible for high data rates, but Insteon shares its low data rates with ZigBee and Z-Wave. Simulcasting is also a result of the fact that an Insteon network does not have a master/slave relationship. Every node has the ability to send and receive messages without having a controller. This makes it possible to have any number of devices in a network without being restricted by a maximum number of connections to a controlling device.

One thing Insteon is lacking compared to ZigBee and Z-Wave is third party support for their devices. They manufacture almost all of their own devices, which leads to a limited amount of choice in terms of different types of devices designed for the same task.

A unique advantage of Insteon is the ability to interface with devices following the X10 protocol. The X10 protocol was one of the original protocols designed to work using only power lines<sup>76</sup>. It is outdated now in terms of being a reasonable choice for a new system, as it was designed over 30 years ago. This means that there is no wireless communication involved, which is essential for a modern day smart home communication protocol. That said, there are many legacy automation systems in place which still use X10 devices. If support for these legacy systems was needed for this project, then Insteon would be a competitive choice for our communication protocol.

## C-4 WiFi

### Description

WiFi is by far the most common communication protocol used in a home on a daily basis. Nearly every other communication protocol is compatible with WiFi devices, and they tend to be easy to install. There are several pros and cons associated with using WiFi for home automation, which are outlined below.

### Technical Overview

WiFi operates using a star network topology<sup>77</sup>. Every node is connected to a central server node. All communications go from the source node, through the central server node, and arrive at the destination node. This means that if the central server goes down, no messages can be passed, leading to potential stability issues. Because messages cannot be routed through intermediate nodes, the communication range must generally be much larger than in a mesh network. WiFi also boasts substantially higher data transmission rates than the communication protocols discussed previously. A WiFi (802.11b) connection can transfer data at a rate of 54 Mbps at a range of 100 meters<sup>78</sup>. As stated earlier, WiFi typically operates at a frequency of 2.4 GHz.

The biggest advantage of using WiFi for home automation is the simplicity. There is virtually no limit to the number of devices that are WiFi compatible, as devices using nearly every other big communication protocol for home automation are also compatible with WiFi. It also requires no extra hardware to communicate with WiFi, which reduces the complexity of setting up hardware. Non-technical users are still generally familiar with WiFi, making the setup process easier.

An issue with using WiFi for home automation is that in terms of required range and data transfer specifications, it is overkill<sup>79</sup>. WiFi is designed with high intensive data transfer in mind, which home automation systems do not take advantage of. A WiFi device needs to provide enough power to operate with these specifications, leading to a large increase in power consumption. If the device is battery powered, it will drain much more quickly than if it were using one of the above protocols.

Another issue stems directly from the prevalence of WiFi. Having a smart home network sharing a WiFi network with regular household uses can cause the network as a whole to slow, due to the bandwidth being shared across so many devices<sup>80</sup>.

## C-5 Bluetooth

### Description

Bluetooth is the most similar to WiFi of the alternative options. It is fairly common in households, and non-technical users are more likely to be familiar with it than other protocols. There are two main classifications of Bluetooth when it comes to home automation, both of which will be discussed below.

### Technical Overview

Bluetooth operates in the 2.4 GHz frequency band, alongside WiFi and ZigBee. Bluetooth also shares the star network topology with WiFi, and is ideal for master and slave devices<sup>81</sup>. This can lead to the same interference problems as discussed in the WiFi and ZigBee sections. As the number of devices on the same radio frequency increases, the competition for bandwidth also increases, causing potential latency and interference. The range and data transfer rate for Bluetooth ranges from 1 Mbps and 10 meters to 24 Mbps and 100 meters<sup>82</sup>. All of these data transfer rates are acceptable for a smart home system. The range on the earlier versions of Bluetooth is potentially very restricting. Bluetooth is somewhere between WiFi devices and ZigBee/Z-Wave devices in terms of power consumption.

There is another choice for Bluetooth that addresses some of the issues above. Bluetooth version 4.0, also branded as

Bluetooth Low Energy (BLE). This is a direct competitor with ZigBee and Z-Wave. The range for a BLE device is 50 meters and BLE is able to take advantage of a mesh network topology <sup>83</sup>. The maximum data transfer rate 1 Mbps in theory, but it is generally much lower than that in practise. BLE splits the 2.4 GHz channel into smaller sub-channels to help avoid interference with WiFi channels.

One of the goals of BLE is to make devices that do not require constant data transmission more efficient. It accomplishes this by closing inactive connections while no data is being transferred. Once data needs to be transferred, it reestablishes the necessary connection, completes the transfer, and closes the connection again <sup>84</sup>.

## C-6 Summary

### Evaluation Criteria

Protocol	Transfer Rate	Battery Life	Interoperability	## of Connections	Frequency	Range	Topology
ZigBee	250 kbps	Good	Good	256	2.4 GHz	35 Ft.	Mesh
Z-Wave	40 kbps	Great	Great	232	915 MHz	100 Ft.	Mesh
Insteon	13 kbps	Good	Bad	N/A	915 MHz	150 Ft.	Mesh
WiFi	54 Mbps	Bad	Great	256	2.4 GHz	105 Ft.	Star
BLE	10 kbps	Good	Great	9	2.4 GHz	200 Ft.	Star

As stated above, the goal of this research was to pick an appropriate protocol for our system. One of the differing attributes between the protocols is the data transfer rates. The required data rate for most smart home devices is minimal, and a higher data rate demands more power. The data rate provided by WiFi is more than required for our project so it will not be the primary communication protocol used. That being said, WiFi compatibility is important to this project because of its prevalence in homes, and because of the enormous amount of devices that communicate over WiFi.

Having as inclusive device support as possible is a key aspect to our project, as it allows a user to have whatever functionality they desire. This heavily influenced us in deciding not to use Insteon as our primary protocol, as the backwards compatibility with X10 power line communication protocol is not something we require.

ZigBee and Z-Wave are very similar, with the key difference in our eyes being the consistent interface that Z-Wave devices provide for controlling them. In additionally, avoiding interference conflicts between the prevalent communication protocol, WiFi, is a benefit. Z-Wave operates in the less used 900 MHz frequency band, avoiding any potential conflicts.

A mesh network topology has many benefits over a star topology for message routing and communication in home automation systems. The stability offered by a mesh topology is aids in reliability, and the amount of data transmission is low enough that the redundant connections are not costly. This makes Z-Wave a more attractive alternative than Bluetooth Low Energy.

Overall, using Z-Wave as our primary communication protocol appears to be the best choice for this project. For industry compliance, WiFi will be required as well.

### Z-Wave Implementation Specifics

Any processing unit with USB support can be easily turned into a Z-Wave master, using a Z-Wave USB stick. Converting an Arduino into a Z-Wave slave is not simple. There are specialized Arduino boards that have the Z-Wave protocol built in. Another option is to attach a radio frequency device to an Arduino, and to implement the Z-Wave stack protocol manually. The easiest way to have Z-Wave slave devices is simply not to make them, but to buy them.

## D Custom-Built Devices

### Background

The purpose of this section is to present our investigation into the process of building various types of smart devices which might be of use for home automation. The purpose of this investigation is to provide information that the team can use to decide which devices will be included in the system to showcase its machine learning capabilities. In particular, this section will examine the feasibility of assembling such devices from basic electronic components, rather than purchasing a commercial device.

In this section, a **smart device** refers to a sensor or actuator which can be controlled over a wireless network. The process of building a smart device is expected to consist of interfacing a hardware module with a microcontroller which is capable of controlling the device and communicating over a network.

Evaluation of custom devices will focus on the following characteristics:

### **Expertise required**

How difficult is it for a team of software engineering students to build the device? Some complex devices will be impractical for the team to build due to the lack of hardware knowledge. Factors which will be considered in the evaluation of the devices include the availability of tutorials and development kits. Safety will also be a critical factor (Does the team have the facilities and expertise necessary to build the device safely).

### **Level of Effort**

In order to allow the team to focus on the machine learning aspects of the system, devices which can be used to demonstrate the system must be available quickly. In order to measure this criteria, the amount of effort required to build an LED controlled through a voltage relay will be used as a baseline for estimation. The following scale will be used:

#### **Low**

- Comparable to baseline (less than a day of work)

#### **High**

- High effort (A couple days)

#### **Extreme**

- Extreme effort (many days or weeks)

### **Quality Comparisons**

Commercially available devices may offer features which could be useful to demonstrate the system, but are difficult to include in a custom-built device. It will be useful to determine whether or not the devices described by most custom-build tutorials are fully featured. In some cases, the features of a typical custom-built device will be compared against several commercial options.

### **Devices of Interest**

This section contains a list of device types which were investigated, and a short explanation of why the devices could showcase the machine learning capabilities of the system. In general, we believe that in order to showcase the machine learning capabilities of the system, it will be important to include a wide range of sensors, as well as actuators whose desired states may be influenced by several unrelated sensors. By providing such a range of devices, we hope to demonstrate that the machine learning algorithm is capable of identifying more complex interactions between devices than a simple IFTTT relationship.

In addition to providing a varied range of sensors, we would like to provide several sensors and actuators with non-binary inputs and outputs. The interactions between such devices may be more complex than for binary devices due to the increased number of possible states.

This section investigates some smart devices which are potentially within the team's ability to build.

### **Motion Sensors**

Many actions could be triggered by a person entering or leaving a house or a room. A motion sensor could potentially interact with every other device on this list. Due to the wide range of potential interactions, we expect that a motion sensor will be a good test of the machine learning component's ability to determine the relationships between inputs and outputs. The motion sensor could also reveal flaws in the machine learning algorithm. For example, the machine learning algorithm may determine that when a motion sensor is triggered outside a homeowner's bedroom, the coffee machine should be turned on. However, this behaviour would only be desired during certain hours of the day (the coffee machine should not turn on when the homeowner goes to bed, for example). It is likely that there are many such scenarios that we haven't thought of which would present challenging cases for the machine learning component to handle.

### **Thermostat**

The setting of a thermostat may be affected by several different factors, such as temperature, time of day, and light levels. Since thermostats are also a non-binary output device, their behaviour when controlled by the machine learning algorithms may be more varied than other devices.

## Light Sensor

A light sensor provides a non-binary input to the machine learning component. Similar to a motion sensor, the level of light in a room may be related to the behaviour of many other devices.

## Dimmer Switch

A variable-voltage switch is an example of a non-binary output device. A variable-voltage switch could be used to control the brightness of lights, or the speed of a fan.

## Coffee Makers

The coffee maker could be turned on in response to several different input devices (light sensor, motion sensor)

## D-1 Motion Sensor

### Technical Overview

This section considers devices that can be used to alert the system when a person enters or leaves an area of the home.

### Sensor Technologies

This section provides a comparison of several different sensor technologies that are commonly used in motion detection.

#### Passive Infrared (PIR)

A passive infrared sensor detects motion using the infrared radiation (heat) from a warm body. A sensor contains two slots, each of which contains a material which is sensitive to infrared radiation. As a warm body passes in front of the sensor, a different amount of radiation is received at each slot. This difference in radiation causes a signal in the output of the device.

Use of the PIR modules encountered during this research does not require expert knowledge of circuit design; the complexity of the circuits involved in connecting the modules to a microcontroller is comparable to that of a simple LED circuit. A power source and a resistor is sufficient to get the module up and running.

Most PIR modules have 3 pins to connect to a circuit. One pin connects to ground, another to power, and the third pin is used for output. The output consists of a single digital signal indicating when motion is detected.

Tutorials describing how to connect PIR modules to common microcontrollers, such as a Raspberry Pi or Arduino are widely available online.

The complexity of the circuit required to interface with a PIR module is comparable to the light switch circuit, consisting of a single push button used to toggle an LED. Therefore, development time required for the complete device is expected to be under 10 hours.

PIR sensor modules are reliable because they do not typically contain any moving components, other than potentiometer used for sensitivity adjustment.

PIR sensors are easy to use, the main difficulties that a user may encounter in setting up a PIR sensor are ensuring that the detector's field of view covers the correct area, as well as potentially adjusting the sensitivity of the detector.

PIR sensors are available with a range which is suitable for a typical room (approximately 7m range).

The following tutorials explain how to interface with PIR modules:

<https://cdn-learn.adafruit.com/downloads/pdf/pir-passive-infrared-proximity-motion-sensor.pdf> <https://learn.adafruit.com/pir-passive-infrared-proximity-motion-sensor/>

#### Doppler-Effect based sensors

Several types of motion detectors use the Doppler effect to detect motion. The detector transmits a signal of a known frequency. This signal is reflected by any objects in its path and detected when it returns to the sensor. The sensor tracks the frequency of the reflected wave; when a wave is reflected off of a moving object the frequency of the reflected wave differs from that of the incident wave due to the Doppler effect. This change in frequency is detected by the sensor and registered as motion.

#### Infrared Break-Beam

An infrared break-beam sensor consists of two physical modules separated by some distance. One side of the detector transmits a beam of infrared light which is detected by the other side.

### Expertise Required

- Little expertise required, circuits are simple
- Tutorials widely available online

### Component Availability

- Components widely available

### Reliability

- Sensors generally have a lower range than PIR sensors, availability of detectors with a longer range may be lower
- Allows for finer control over the area of detection than a PIR sensor

### Usability

- More difficult setup than a PIR sensor, requires the user to precisely aim the transmitted beam.

### Feature Comparison

Feature	Custom	D-Link Wifi Motion Sensor	Samsung SmartThings Motion Sensor	Belkin
Range	7m	8m	15m - 40m	3m
Interfaces	—	WiFi	ZigBee	WiFi
Type	PIR	PIR	PIR	PIR

Note: The custom device can potentially support multiple different communication interfaces

### Evaluation

Criterion	Score
Expertise Required	Low
Level of Effort	Low
Quality Comparison	Equal

## D-2 Variable-Voltage Switch

The characteristics of variable-voltage switches vary significantly depending on the type of device that the switch is expected to control (DC vs AC).

### Controlling DC power

If the type of device being controlled requires DC power input, the amount of power supplied to the device can be controlled using pulse-width modulation (PWM). A digital output is used to create a square wave. By varying the frequency of the square wave, it is possible to simulate the application of a steady voltage between the pin's high and low voltages.

Limitations to simple PWM

- Power available to the device is limited by the power supplied by the controlling device - Limited to DC devices

### Expertise Required

Minimal expertise is required to use PWM to control a device. The circuits required are as simple as the circuits required to power a simple LED.

### Reliability

Simple PWM circuits are limited to controlling devices with low power requirements. While the technique is reliable for devices which meet the power requirements, such as LED lamps, the power requirements of most home devices means that the applicability of this technique will be severely limited. Most devices are intended to be connected to a wall socket, meaning that they are expecting AC current, which is a significantly higher amount of power than is available from a microcontroller such as an Arduino.

### Controlling AC power

### Expertise Required

- Safety concerns: Controlling devices which expect to receive the voltages available from a wall socket means dealing with high voltages. Without any team members trained in using high voltages, building a device to control high voltages is a very serious safety risk.
- Lack of trusted tutorials: For most of the circuits considered during this research, it has been possible to find tutorials online from trusted sources, such as the official Arduino website.

### Level of Effort

- When it was possible to find a tutorial online for building a circuit to control AC voltages, the circuit was found to be much more complex than the simple light switch circuit. Due to the amount of time required to fully understand these circuits, it is estimated that effort required is high.

Feature	Custom	GE Smart Dimmer	Z-Wave	Plugin-in	Philips Hue Dimmer Switch	Lutron Caseta Wireless Lamp Dimmer	Plugin-In
Compatible Devices	AC devices	AC devices			Philips Hue Products	AC Devices	
Interfaces	–	Z-Wave			ZigBee	Lutron Integration Protocol	

### Evaluation

Criterion	Score
Expertise Required	High
Level of Effort	High
Quality Comparison	Equal

Note: There are safety concerns for custom-building this device

## D-3 Light Sensor

### Description

This section investigates devices which can detect the amount of ambient light in an area of the house.

### Photoresistors

Light sensors generally make use of a component called a photoresistor. The resistance of a photoresistor differs depending on the amount of light incident to the component. Photoresistors are also called photocells.

### Reliability Characteristics

- Photoresistors are unsuitable for precise lighting measurements because its resistance may vary due to temperature as well as light
- Photoresistors may exhibit latency (delay between a change in light and a change in resistance)

### Photodiode

Photodiodes are components which can be used similarly to photoresistors to detect light. A photodiode allows electrons to pass when there is light shining on it. The current allowed to pass is proportional to the amount of light incident on the device.

Unlike photoresistors, a photodiode is not sensitive to temperature changes and may allow for more accurate light detection. The circuit required to interface with a photodiode is of similar complexity to the circuit required to interface with a photoresistor.

### Expertise Required

Minimal expertise is required to build the devices described by most guides and tutorials. The circuit is not significantly more complex than the light switch.

### Level of Effort

Due to the simplicity of the photoresistor circuit and the wide availability of the required components and tutorials, a custom-built light sensor is required requires a low amount of effort.

### Feature Comparison

Many commercially available light sensors are included in combination devices which include several different types of sensors. Commercial solutions provide very little data about the range of light that their products can detect. For a custom built solution, the range of detectable light depends on combination of the particular photocell chosen. Assuming that both a custom device and most commercial devices are able to differentiate between daytime and evening levels of light, additional features available from commercial devices are generally related to other types of sensors

### Evaluation

Criterion	Score
Expertise Required	Low
Level of Effort	Low
Quality Comparison	Equal

## D-4 Thermostat

This section considers controlling a typical wall-mounted thermostat using a microcontroller such as an Arduino.

### Expertise Required

Safety: Controlling a wall-mounted thermostat means working with mains voltage levels. Without knowledge in using high voltages, building this device is a significant safety risk

### Effort Level

Due to the lack of trusted tutorials online, as well as the wealth of features that users are used to having in a thermostat, the time investment required to build a fully-featured thermostat is extreme.

### Evaluation

Due to the extreme level of effort required and the safety concerns with building a thermostat, a custom-built thermostat is not feasible for this project.

## D-5 Alarm Clock

There are a large variety of features available for alarm clocks, this section will focus on a simple alarm clock that beeps at a programmed time of day. The clock should have manual (button) input in order to allow the user to set alarm times so that the machine learning component can be trained. More sophisticated clocks are expected to be much too complex for the team to build.

After review of many online tutorials for building alarm clocks, a common structure for a clock circuit has been identified.

The basic alarm clock circuit generally requires the following components:

- LCD display
- Microcontroller
- Piezo Buzzer or Speaker
- Varying numbers of push buttons for manual configuration

### Level of Effort

Due to the need to interface with an LCD display, and because of the large number of components, a custom build of an alarm clock is expected to be more complex than the light switch. The level of effort is estimated to be high because of this.

### Feature Comparison

Homeowners may be used to alarm clocks with nice interfaces, often in the form of an app on their phone. The custom alarm clocks investigated have significantly inferior interfaces, making use of a 4-button interface to set the time. The clocks considered here also lack features such as adjustable alarm sounds, configuring multiple alarms, and setting weekly alarm schedules. Making a custom built alarm clock as usable as commercially available clocks would require significant time investment.

## D-6 Coffee Makers

### Using a Relay Switch

A simple way to connect a coffee machine to a microcontroller is by using a voltage relay. A voltage relay is an electrically controlled switch for high power devices. A simple coffee machine that only needs to be plugged in in order to start brewing could be controlled using a simple voltage relay circuit.

### Level of Effort

The same circuit which is used in the LED switch could be used to control the coffee machine, since both the coffee machine and LED can be connected to the same voltage relay, so the level of effort required is low.

### Required Expertise

- Safety risks: Coffee machine are normally connected directly into a wall socket. Controlling the coffee machine using a voltage relay would therefore involve high voltage levels which are unsafe to work with without proper training

In order to interface a microcontroller with more sophisticated coffee machines, some level of reverse engineering of the coffee machine's control circuits would be necessary. This would greatly increase the amount of time necessary to create the device, due to the lack of electronics knowledge on the team.

### Evaluation

Custom builds of both simple and fully-featured coffee makers may be infeasible due to safety concerns when controlling high voltage devices.

## D-7 Summary

Device	Level of Effort	Safety Concerns	Fully-Featured
Motion Sensor	Low	None	Yes
Light Sensor	Low	None	Yes
Dimmer Switch	Low	High Voltage	Yes
Coffee Maker	High	High Voltage	No
Thermostat	High	High Voltage	No
Alarm Clock	Low	None	No

### Conclusions

It is feasible for the team to build motion sensor, light sensors, and an alarm clock if no acceptable commercial solution is available. We should avoid building dimmer switches, coffee makers, and thermostats due to the potential high-voltage work involved and the lack of electronics knowledge available.

## E Smart Devices

### Background

In the context of this project, a smart device is a device that is capable of communicating over a wireless computer network, such as WiFi or Z-Wave. Each device provides a set of inputs and outputs which can be controlled and examined using some protocol.

## Relation to System

This section examines several commercial smart device products which are available off-the-shelf. The goal of this research is to determine what types of devices are commercially available, and to compare alternative products which have similar functionality. By purchasing off-the-shelf smart devices, the development time for the project can be focused on building the machine learning features, which differentiate our product from many existing automation systems. An awareness of existing smart devices will also allow us to select common technologies to support in the system. Support for commercial smart devices makes our system more appealing to the end user because they are not limited to only using devices we create.

Where possible, research will focus on answering the following questions about a product or line of products:

- What inputs and outputs does the device have? What type of information can the device provide to the machine learning algorithm, and what can be controlled?
- Which communication protocol(s) are supported by the device?
- Are the interfaces used to communicate with the device well-documented? Are there tutorials and SDKs available?
- What restrictions does the device introduce to the system? For example, do users need to create an account with another company in order to use the device with our system?

## E-1 WeMo

### Description

WeMo is a line of smart devices made by Belkin. WeMo devices can be controlled over a WiFi connection using a smartphone app.

### Available Devices

1. Light switch
  - On/Off
1. Outlet switch
  - On/Off
1. Camera
  - On/Off
  - Motion detection
1. LED lights
  - On/Off
  - Dimming
1. Slow Cooker
  - On/Off
  - Temperature Control
1. Coffeemaker
  - On/Off
  - Brew status
  - Change filter
1. Air Purifier
  - Fan speed
  - Ionizing On/Off
  - Filter life

#### 1. Humidifier

- Humidity level
- Water status
- Filter status

#### 1. Heater

- On/Off
- Temperature
- Power level

### Technical Overview

#### Communication Protocol

WeMo only supports WiFi for communicating with devices. No central hub is required in order to control WeMo devices, each device connects to a WiFi network directly.

WeMo uses Universal Plug And Play (UPnP) protocol for discovery and operating the devices.

#### Developing with WeMo

- *ouimeaux* is an Open source python API for controlling WeMo devices.
- WeMo devices can be controlled using UPnP. This allows us to implement one protocol and communicate with all WeMo devices as well as any other smart devices from other vendors that use UPnP.

#### Research Criteria

All WeMo Devices

Inputs	Outputs	Developer Support	Protocol	API Restrictions
On/Off	On/Off	ouimeaux library	WiFi	Local Only
			UPnP	We need to Write it

### E-2 Nest Thermostat

#### Description

The Nest thermostat is a smart learning thermostat. Over time the thermostat learns the homeowner's routine and adjusts the temperature accordingly. The thermostat also turns off automatically when it detects that nobody is home, and can be remotely controlled using a smartphone app.

#### Technical Overview

Nest communicates using WiFi and a custom nest protocol called **Nest Weave**. Nest Weave uses WiFi and the Thread protocol.

Nest provides API support through the nest cloud. The API is accessed as a RESTful service or using Firebase.

#### Evaluation

The nest thermostat already has some machine learning on it. Trying to control it using our algorithm could cause unexpected results. They also require the use of a cloud API to control the thermostat and we are trying to avoid this and communicate locally with our devices. Due to these reasons it seems like the nest thermostat is not a great fit for our system and we should not invest time into integrating with it.

### E-3 Honeywell VisionPro Thermostat

#### Description

The Honeywell VisionPro Thermostat is a smart programmable thermostat which can be controlled using the Z-Wave protocol. Unlike the Nest thermostat, the VisionPro does not include learning features.

## Technical Overview

### Communication

The thermostat communicates can be controlled through the touch screen or through Z-Wave.

### API

There is no API provided by Honeywell. The thermostat is controllable using the Z-Wave protocol.

### Evaluation

This is a simple thermostat that will be easy to control using Z-Wave and as it doesn't have any learning on it, so there won't be any conflicts with our system.

## E-4 Wireless Speakers

### Available Devices

Speakers that have the capability to provide actions performed to our communication hub are required to automate music in a home. There does not appear to be any Z-Wave ready speakers available currently, and existing WiFi speakers do not provide an API to interact with them. The result of this is that appropriate speakers for use in our system do not currently exist.

### Developing Wireless Speakers

It could be possible to create our own smart speakers for use in the ARIA system, but it would require a large amount of effort. Development would involve using an Arduino or similar microcomputing device to turn a speaker into a device compatible with our system. This implies that the speaker must be able to communicate using our own defined protocol. Implementing this is not a priority for our project, as the value added is limited, but it can be considered in the future if there is necessary need. To include smart speakers in our home automation system we will need to explore developing our own custom devices.

## E-5 Smart TV

### Available Devices

Similar to the wireless speakers, there are no available TVs that provide the required functionality to be a useful device in our system. Creating custom TV devices is also non-feasible, as the level of complexity for interfacing with a TV and the corresponding cable box exceeds the capabilities of our team members.

## E-6 Philips Hue

### Available Devices

#### 1. White Bulbs

- On/Off
- Dimming

#### 1. White Ambiance Bulbs

- On/Off
- Dimming
- Supports multiple shades of white

#### 1. Colour Ambiance Bulbs

- On/Off
- Dimming
- Configurable colour

#### 1. Lightstrips

- Adhesive strips of LED lights

- Dimming
- Configurable colours
- Dynamic lighting/colour schemes
- White light not supported

#### 1. Lightstrip Plus

- Adhesive strips of LED lights
- Dimming
- Configurable colours
- Dynamic lighting/colour schemes
- Supports white light
- Brighter than regular Lightstrips (1600 Lumen)
- Fine-grained fading control

#### 1. Dimmer switch

- Battery-powered
- Doesn't require the Hue bridge
- Can't use it with other AC devices, no electrical contact with bulbs

#### 1. Tap Switch

- Powered by touch - no battery or wires
- Hue bridge and app required

#### 1. Hue Motion Sensor

- Detects motion in the vicinity of a PIR sensor
- Includes an integrated daylight sensor

### Developing with Hue

- Devices use ZigBee Light Link
- The Hue bridge is a hub device that allows lights to be controlled using WiFi. It bridges the ZigBee protocol used by lights to Wifi used by apps.
- Bridge works with most standard ZigBee lights
- Hue Bridge provides a RESTful API for controlling connected lights. API is only accessible when you're on the same LAN as the bridge.

### Research Criteria

Inputs and outputs differ by device type; developer support, communication protocol, and API restrictions are common to all Philips Hue devices.

#### Hue Lights

Inputs	Outputs	Developer Support	Protocol	API Restrictions
On/Off	On/Off	Tutorials on Hue website	ZigBee	Local Only
Brightness	Brightness	Android, Java, IOS Official SDKs		REST API requires a hub
Hue	Hue	Numerous 3rd party SDKs		
Saturation	Saturation			
Colour Temperature	Colour Temperature			
Dynamic Effect	Dynamic Effect			

#### Hue Motion Sensor

Inputs	Outputs
sensitivity	presence
	light level

#### Hue Dimmer Switch, Hue Tap

Inputs	Outputs
	button event

## E-7 Osram LIGHTIFY

### Description

LIGHTIFY is a line of lighting products which can be controlled using the LIGHTIFY mobile app. LIGHTIFY provides two separate product lines; LIGHTIFY Pro and LIGHTIFY Home. LIGHTIFY Pro products are designed to be highly scalable for office environments. This research focuses on the LIGHTIFY Home line of products.

The LIGHTIFY system consists of a gateway device which connects to all of the bulbs installed in the home. Using the LIGHTIFY app, a homeowner can control connected lights from a mobile device.

### Available Devices

#### 1. Surface Light TW

- Dimmable
- Adjustable colour temperature
- White only

#### 1. Surface Light W

- Dimmable
- White only

#### 1. Flex RGBW

- RGB colour control
- Adjustable colour temperature
- Dimmable

### Technical Overview

LIGHTIFY products use the ZigBee protocol for communication between the gateway and lighting products. The gateway connects to a local Wifi network, allowing the LIGHTIFY app to control the system over the Internet.

Due to the use of the open ZigBee protocol, LIGHTIFY products can be controlled using any ZigBee controller

The LIGHTIFY gateway also provides a RESTful API for controlling lights over internet. One notable limitation of the LIGHTIFY API is that it is a cloud-only API. This means that the LIGHTIFY gateway is strongly tied to a homeowner's LIGHTIFY account; Osram does not document any local-only API for controlling devices using a gateway

#### Research Attributes

Inputs	Outputs	Developer Support	Protocol	API Restrictions
on/off	on/off	REST API description	ZigBee	REST API is Cloud Only
colour	colour	Sample Application		REST API requires LIGHTIFY account
colour temperature	colour temperature	No Official SDKs		REST API requires a hub
brightness	brightness			
saturation	saturation			
transition time (effects)	transition time			

### E-8 Aeotec Light Bulbs

#### Description

Aeotec sells light bulbs which are compatible with the Z-Wave protocol. Aeotec products are compatible with most Z-Wave hubs. Aeotec does not provide a proprietary API for their products.

#### Available Devices

##### 1. LED Bulb

- Dimmable
- Configurable Colour

##### 1. LED Strip

- Dimmable
- Configurable Colour

#### Research Attributes

Inputs	Outputs	Developer Support	Protocol	API Restrictions
on/off	on/off	Not Aeotec Specific	Z-Wave	None
colour	colour	Z-Wave Developer		
brightness	brightness			

### E-9 Aeon Labs

#### Description

Aeon Labs is a company that produces a large variety of Z-Wave devices. They also provide the ability to create your own home automation hub.

#### Technical Overview

Aeon Labs produce a USB dongle that allows you to turn any computing device into a Z-Wave communication hub. This hub

allows the user to manually control any Z-Wave device on the Z-Wave network, and provides the functionality to add and remove devices to/from the network. To add a Z-Wave device, start by unplugging the dongle from the hub and pushing the button on it. Then walk to the new device and push the button on the device. The dongle must also be unplugged to remove a device from the network. To put it in removal mode, push and hold the button on the dongle. Then go to each device you wish to remove from the network and push the button. The dongle can be bought for about \$60.

They do not provide their own hub, which is ideal for our project. They simply allow the ability to turn a computing device into a custom hub by providing the required RF signal to communicate with Z-Wave devices. To begin development for Z-Wave devices, The list of Z-Wave devices from Aeon Labs alone is fairly extensive. The list include but is not limited to: door sensors, window sensors, lights, energy meters, range extenders.

The specification for interacting with Z-Wave devices is public, and available at <http://zwavepublic.com/specifications>. There is also an open Z-Wave sdk available, to communicate from the controller to devices.

### Available Devices of Interest

#### 1. MultiSensor

- Motion Sensor
- Temperature Sensor
- Light Sensor
- Humidity Sensor
- Vibration Sensor
- UV Sensor

The MultiSensor is a Z-Wave device, meaning that it follows the Z-Wave protocol for commands interacting with each individual sensor. As stated above, the specification for interacting with Z-Wave devices is available at <http://zwavepublic.com/specifications>.

Individual Z-Wave sensors are also available, and function using the same specifications as the MultiSensor above. AARTech is one alternative which has a selection of individual sensors if the MultiSensor is unnecessary.

#### 1. Door / Window Sensor

- Detect window/door state The Door/Window sensor is purposed to be able to detect the state of doors or windows. This allows the system to use information about the state of doors and windows to make decisions about what actions to take.

### Evaluation

Aeon Labs is an ideal solution for our project. To start, there is an easy way to set up our own hub, instead of being constrained to buying one. This allows us to implement the features we want, and add support for protocols we want without restriction. Having access to an sdk is very important to us as well. It lets us not be responsible for implementing the Z-Wave stack protocol, while also giving us the freedom to use the information received by the devices in a unique way. Specifically, this will provide us with data for the machine learning algorithm.

## E-10 Passive Infrared Sensor

### Description

A passive infrared sensor (PIR) is a device that can be used to detect if there are people in a room or not. They are available to buy Z-Wave ready, and can be used as a motion sensor in a home environment.

### Technical Overview

A PIR creates a binary output based on if the sensor is being triggered or not. This makes it useful as a motion detector, as well as being able to detect if people remain present in a room. It is also feasible easy to develop our own PIR sensors, which is discussed in the Custom Devices section of the Appendix.

### Evaluation

These devices will be useful in our system whenever it is necessary to detect the presence of a person in an area. There is a large selection of PIRs available to buy that are Z-Wave compatible, and it is also an option to construct our own.

## E-11 Spruce Irrigation

## **Description**

Spruce irrigation is a home plant watering automation system. The irrigation system can be used outdoors for watering gardens, lawns or any other plant life. The Spruce system is ideal for scheduling or automating plant watering cycles. The Spruce system also offers automation of water based on weather conditions and soil moisture.

## **Technical Overview**

The Spruce irrigation system uses a combination of wireless sensors, smart sprinklers and a central hub for controlling the watering levels of its plants. The irrigation system's central hub is connected to each of the smart sprinklers to control the water flow. Smart sensors are then placed in various locations on the property and communicate wirelessly to the central hub. The sensors are placed in the ground and are battery powered.

The Spruce hub provides manual control of all the sprinklers in the system. The hub also provides a user interface for scheduling sprinkler times and amounts. The Spruce system is also equip with some learning software that uses weather predictions and moisture amount to optimize water use for watering plants.

## **Evaluation**

The Spruce system provides integration to SmartThings but has no other public APIs. This means that it is not accessible other systems for communication. The only option for controlling the Spruce system would be to implement the SmartThings protocol or to attach an adapter to an existing SmartThings Hub. This is likely outside of the scope of this project but could be pursued if there was interest.

## **E-12 OSO PlantLink**

### **Description**

PlantLink is a indoor or outdoor plant monitoring and irrigation system. PlantLink uses a simple monitoring system where sensors are placed in the target plant's soil for monitoring. These sensors then report back to a mobile app for monitoring. PlantLink also offers an automated valve for controlling water flow of a hose.

### **Technical Overview**

PlantLink sensors are low power, light weight units that can transmit data with a range of 100-300 ft. The sensor is water resistant and battery powered with an estimated one year battery life. The sensors are used to check soil moisture of the plants they are monitoring. The sensors then communicate to your mobile device using email, text or push notifications.

PlantLink also offers a smart valve system for controlling water flow of a hose. The valve system is solar powered and can be controlled from the PlantLink mobile app. The valve can also communicate directly to sensors to automate the watering of plants. In this mode, if a sensor reports that the soil is dry then the valve will open up and water the plants.

### **Evaluation**

PlantLink is compatible with other platforms but does not offer open source access to its APIs. PlantLink can communicate with SmartThings, Iris, greenIQ and GRO automation systems. To be able to integrate with this system we would need to interface through one of these other systems as an intermediary. The PlantLink system may be outside of the scope of this system unless there we plan on integrating with another smart system

## **E-13 Summary of Evaluation**

Existing devices with an element of machine learning already incorporated in them are not a good fit for our system, as they may cause unexpected results when introduced to our custom machine learning algorithm. Similarly, devices that do not provide an API are also not suitable for use in our system. Without being able to communicate with a device, there is no way for us to control it from our hub or to retrieve data from it for the machine learning algorithm. These aspects rule out devices such as the NEST thermostat and the irrigation systems.

Third party Z-Wave devices are suitable for our system because they provide an easy method of communication in a way that helps enable the machine learning rather than hinder it. Any device that has no special capabilities other than being Z-Wave ready are ideal, because they allow us to use them with no unexpected behaviours. The Honeywell VisionPro Thermostat and devices from Aeon Labs are examples of this.

## F Finances

### F-1 Purchases

Date	Item	Quantity	Unit Cost	Taxes & Shipping	Total
13-11-2016	Z-Wave USB Z-Stick Gen 5	1	\$64.99	\$19.74	\$94.73
13-11-2016	Z-Wave Dimmable LED Bulb	1	\$36.09	\$9.59	\$45.68
24-11-2016	Raspberry Pi 3 Model B Starter Kit	1	\$79.97	\$10.40	\$90.37

### F-1 Purchases

The Aria system required purchasing a number of smart devices in order to adequately construct, test and demonstrate its capabilities. Table F-1 lists the items that have been purchased for the Aria project. These items have been used to develop and test the smart home system.

Table F-1: Purchased Items for Aria Project

Date	Item	Quantity	Unit Cost	Taxes & Shipping	Total
13-11-2016	Z-Wave USB Z-Stick Gen 5	1	\$64.99	\$19.74	\$94.73
13-11-2016	Z-Wave Dimmable LED Bulb	1	\$36.09	\$9.59	\$45.68

04-02-2017	Radio Thermostat Z-Wave Plus	1	\$99.99	\$24.29	\$124.28
<b>Total</b>					<b>\$988.93</b>

## F-2 Funding

In order to make the purchases for the devices required for the Aria project, several funding sources were explored. Table F-2 lists the funds that were applied to for this project, the amount requested and the amount received. All of the funds received from these sources were used to purchase the devices in Table F-1.

Table F-2: Funding Resources for Aria Project

Fund	Accepted	Funding Requested	Funding Received
Student Experience In Engineering and Design (SEED) Fund	Yes	\$983	\$400
Capstone Design Project Fund	Yes	\$983	\$500
CSES Student Group Fund	Pending	\$575	
<b>Total</b>			<b>\$900</b>

## G Scenarios

### G-1 Music Automation

#### Sample Sequence

##### Setup

The home's main entrance is equipped with two break-beam motion sensors in series. The devices are configured so that they provide an estimate of the number of people in the house (OccupancyCount). Each of the main rooms contains an audio sensor (DenAudio, BasementAudio), and a sound system (DenSpeakers, BasementSpeakers). Each room also contains a motion sensor (DenMotion, BasementMotion). The basement is also set up with a strip of coloured smart lights.

##### Training Sequence

With their central hub in training mode, the homeowner arrives at the house with a car full of people. As each person enters the home, the motion sensors at the door notify the central hub that the number of people in the house is increasing. The party moves into the den and turns on some music. DenMotion reports the activity in the den to the central hub. The homeowner lowers the thermostat temperature so that the increased number of visitors doesn't make the house uncomfortable. As the level of conversation increases in the den, the homeowner decides to turn down the music to avoid noise complaints from the neighbour. Throughout the party, DenAudio reports changes in noise level to the central hub. When the homeowner changes the volume of the den speakers, DenSpeaker reports the change in its output to the central hub.

After an hour, half of the party moves to the basement to play some Scrabble. BasementMotion reports the new activity in the basement to the central hub. The Scrabble players decide to turn on some music to get everyone in the mood. BasementSpeakers reports the change in its state to the central hub. The homeowner decides to show off his light strips to his friends, and sets them to a dim red colour to enhance the party ambiance. The light strips report their colour and brightness level to the central hub (BasementLightStrip).

At the end of the night, everyone goes home. All music in the house turns off, the basement lightstrips turn off, and the thermostat is returned to its normal setting.

#### Expected Inputs

The log for this scenario is shown below. This log demonstrates the interactions that would be logged.

```
2017-01-01 19:00:00 OccupancyCount: 1
2017-01-01 19:00:01 OccupancyCount: 2

2017-01-02 01:03:16 BasementSpeaker: Volume 0%
2017-01-02 01:03:17 BasementLightStrips: Off
2017-01-02 01:03:18 DenSpeaker: Volume 0%
2017-01-02 01:05:00 Thermostat: 20 C
...

```

### Expected Behaviour

The next time the homeowner has a Scrabble party, 10 guests arrive at the home. After they step through the door and motion is detected in the den, the den sound system turns on and adjusts its volume to an appropriate level. The thermostat lowers the temperature of the room to 20 degrees. The system continues to adjust the volume of the sound system to match the amount of noise detected in the room.

A group of the partygoers decide to move down to the basement for their game. When motion is detected in the basement, the system turns on the lightstrips to a dim red colour and turns the basement sound system on.

After everyone leaves for the night, BasementLightStrips, BasementSpeaker, and DenSpeakers turn off. Thermostat is re-adjusted to the temperature before the party began.

## G-2 Efficient Lights and Temperature

### Sample Sequence

#### Setup

The home is setup with multiple smart lights (SmartLights) for each room and a smart thermostat (SmartThermostat). Motion sensors are added to the main rooms (MotionBedroom, MotionKitchen, MotionDen) in the home to detect presence. Finally, to detect the ambient light per room, light sensors are added in conjunction with the motion sensors (LightBedroom, LightKitchen, LightDen).

#### Training Sequence

The user starts the day by turning on the lights in the bedroom at 7:00:00 AM. LightBedroom sends a notification to the central hub that the light levels have changed in the room and MotionBedroom sends a motion message to the hub. The hub logs these interactions at 7:00:25 AM.

The user then goes to the den to change the temperature to 22°C at 7:12:00 AM. On the way, the user turns on the den lights. MotionBedroom and MotionDen track the movement and send it to the hub. LightDen sends a message to the hub that it has been turned on and SmartTemperature sends the user's input to the hub as well. The hub receives the motion messages at 7:11:40 AM and 7:11:50 AM followed by the den lights at 7:12:05 AM and the temperature change at 7:12:25 AM.

The user then returns to the bedroom and prepares to leave for the day. MotionBedroom again sends a notification that the user is moving in the bedroom from 7:14:00 AM to 7:30:00 AM. The user then leaves the bedroom and turn the light off on the way out. MotionBedroom stops sending motion requests and LightBedroom sends a message that it has been turned off. The user then heads to the kitchen and turns on the lights to make breakfast. MotionKitchen and LightKitchen send messages to the hub that they have been activated at 7:30:25 AM and 7:30:40 AM. MotionKitchen continues to send motion events from 7:31:00 AM to 7:45:00 AM.

Once the user is done breakfast they are ready to leave for the day. The user turns off the lights in the kitchen and walks to the den. MotionKitchen stops sending messages and LightKitchen signals that it has been turned off. In the den, the user lowers the temperature back to 20°C and turns off the den lights before leaving. MotionDen beings sending messages at 7:45:25 AM while SmartThermostat notifies that it has been changed. As the user leaves, MotionDen stops sending motion notifications and LightDen indicates that it has been turned off.

## Alternate Sequence

The user has the option to program all of the smart devices through the web user interface on a predefined schedule. They can choose to select the desired temperatures throughout the day as well as when the lights should turn off and on. Optionally, the user can manually set values through the web UI in real-time without a pre-configured schedule. These events will be logged as if the user was manually interacting with the physical device.

## Expected Inputs

The log for this scenario is shown below. This log demonstrates the interactions that would be logged. Please note that duplicate messages have been omitted and replaced with ... .

```
2016-10-08 7:00:00 MotionBedroom: Motion Detected
2016-10-08 7:00:25 LightBedroom: Light On
2016-10-08 7:11:40 MotionBedroom: Motion Detected
2016-10-08 7:11:50 MotionDen: Motion Detected
2016-10-08 7:12:05 LightDen: Light On

2016-10-08 7:14:00 MotionBedroom: Motion Detected
...
2016-10-08 7:29:50 MotionBedroom: Motion Detected
2016-10-08 7:29:55 LightBedroom: Light Off
2016-10-08 7:30:00 MotionBedroom: Motion Detected
2016-10-08 7:30:25 MotionKitchen: Motion Detected
2016-10-08 7:30:40 LightKitchen: Light On
2016-10-08 7:31:00 MotionKitchen: Motion Detected
...
2016-10-08 7:44:50 MotionKitchen: Motion Detected
2016-10-08 7:44:55 LightKitchen: Light Off
2016-10-08 7:45:00 MotionKitchen: Motion Detected
2016-10-08 7:45:10 MotionDen: Motion Detected
2016-10-08 7:45:25 SmartThermostat: Change Temperature 22°C
2016-10-08 7:45:30 MotionDen: Motion Detected
2016-10-08 7:45:40 LightDen: Light Off
2016-10-08 7:45:45 MotionDen: Motion Detected
```

## Expected Behaviour

The user wakes up and gets out of bed at 7:10:00 AM. MotionBedroom detects this motion and the hub notifies the LightBedroom turns on at 7:10:05 AM. The hub also notifies the SmartThermostat to change its temperature to 22°C at 7:10:10 AM. The user then gets ready for the day and leaves the bedroom at 7:38:00 AM and heads to the kitchen. MotionBedroom stops sending movement notifications at 7:38:00 AM and MotionKitchen starts at 7:38:15 AM. The hub notifies LightBedroom to turn off at 7:40:00 AM and LightKitchen to turn on at 7:38:20 AM.

The user makes and eats breakfast and leaves at 7:48:00 AM. All motion sensors stop logging motion. The hub turns off LightKitchen and sets the SmartThermostat to 20°C at 7:50:00 AM.

The system will continue to pick up patterns as it learns. The system may begin to relate days of the week to certain events and rely less on the motion sensors. If the user was to consistently wake up at 7:00 AM and turn the lights on every Monday then the system may always turn the lights on at that time on Monday regardless of motion. These other factors will need to be considered while designing this system.

## G-3 Coffee Automation

### Sample Sequence

#### Setup

The home is setup with a motion sensor outside the user's bedroom (MotionBedroom), a motion sensor outside the bathroom (MotionBathroom), a motion sensor outside the kitchen (MotionKitchen) and, a smart coffee machine in the kitchen (SmartCoffee).

#### Training Sequence

The user wakes leaves their bedroom and heads towards the bathroom at 7:00:00 AM. MotionBedroom sends a motion detected message to the hub. The hub logs that MotionBedroom detected motion at 7:00:00 AM. MotionBathroom then sends a motion detected message to the hub. The hub then logs that MotionBathroom detected motion at 7:00:25 AM.

The user then leaves the bathroom and heads back to their bedroom. MotionBathroom sends a motion detected message to the hub. The hub logs MotionBathroom detected motion at 7:15:00 AM. MotionBedroom then sends a motion detected message to

the hub. The hub logs MotionBedroom detected motion at 7:15:25 AM.

The user then heads from their bedroom to the kitchen. MotionBedroom sends a motion detected message to the hub. The hub logs MotionBedroom detected motion at 7:20:00 AM. MotionKitchen sends a motion detected message to the hub and the hub logs MotionKitchen detected motion at 7:21:00 AM. The user then turns on the coffee maker. Coffee sends a start brewing message to the hub at 7:21:30 AM. When the coffee is done, SmartCoffee sends a done message to the hub. The hub logs that SmartCoffee finished at 7:27:30 AM.

### Alternate Sequences

There are a few different ways that the coffee maker could be setup to make coffee instead of being turned on manually. It could be scheduled to start at a specific time or it could be started by the user when they get up through the web UI. The difference in the logs for both these cases is simply when the log for the coffee starting and coffee done appear.

### Expected Inputs

The logs for the training scenario would look like the following:

```
2016-11-04 7:00:00 MotionBedroom: Motion Detected
2016-11-04 7:00:25 MotionBathroom: Motion Detected
2016-11-04 7:15:00 MotionBathroom: Motion Detected
2016-11-04 7:15:25 MotionBedroom: Motion Detected
2016-11-04 7:20:00 MotionBedroom: Motion Detected
2016-11-04 7:21:00 MotionKitchen: Motion Detected
2016-11-04 7:21:30 SmartCoffee: Starting
2016-11-04 7:27:30 SmartCoffee: Done
```

This sequence would occur every weekday possibly with the coffee maker being scheduled on one day and the user starting the coffee maker from the web UI. A sample 5 days of logs could look like the following:

```
2016-11-07 7:00:00 MotionBedroom: Motion Detected
2016-11-07 7:00:25 MotionBathroom: Motion Detected
2016-11-07 7:15:00 MotionBathroom: Motion Detected
2016-11-07 7:15:25 MotionBedroom: Motion Detected
2016-11-07 7:20:00 MotionBedroom: Motion Detected
2016-11-07 7:21:00 MotionKitchen: Motion Detected
2016-11-07 7:21:30 SmartCoffee: Starting
2016-11-07 7:27:30 SmartCoffee: Done

2016-11-08 7:05:00 MotionBedroom: Motion Detected
2016-11-08 7:05:30 MotionBathroom: Motion Detected
2016-11-08 7:20:00 MotionBathroom: Motion Detected
2016-11-08 7:20:25 MotionBedroom: Motion Detected
2016-11-08 7:23:00 WebUI: Start Coffee requested
2016-11-08 7:23:10 SmartCoffee: Starting
2016-11-08 7:29:30 SmartCoffee: Done
2016-11-08 7:30:00 MotionBedroom: Motion Detected
2016-11-08 7:31:00 MotionKitchen: Motion Detected

2016-11-09 7:02:00 MotionBedroom: Motion Detected
2016-11-09 7:02:30 MotionBathroom: Motion Detected

2016-11-11 7:20:00 MotionBathroom: Motion Detected
2016-11-11 7:20:25 MotionBedroom: Motion Detected
2016-11-11 7:15:00 MotionBedroom: Motion Detected
2016-11-11 7:16:00 MotionKitchen: Motion Detected
2016-11-11 7:16:30 SmartCoffee: Starting
2016-11-11 7:22:30 SmartCoffee: Done
```

### Expected Behaviour

From the logs the Aria system should be able to tell that the user's morning consists of going to the bathroom, going back to their room then going to the kitchen and having coffee. The system can determine that the average time it takes the user for waking up until they get to the kitchen is 19 minutes and a pot of coffee takes 6 minutes to make. Therefore it is expected when the system is in playback mode that it would start the coffee maker 13 minutes after it sees that MotionBedroom and MotionBathroom have been triggered if it is around 7:00 AM.

As the system gains more and more information there could be some other patterns that the system notices. For example it could be more accurate to only consider other mornings for the current day of the week when calculating the average time to kitchen. For example Wednesdays the user takes less time in the bathroom so there average time to kitchen on Wednesdays is closer to 15 minutes. The system should then on Wednesdays start the coffee maker 9 minutes after the user gets up. There could also be factors from time of year. The users routine could change depending on the month/season these are factors we need to consider while designing the learning algorithm.

## G-4 Effortless Home Lighting

### Sample Sequence

#### Setup

The home is setup with a PIR in the home owner's office (PIROffice), a light sensor in the office (LightOffice), and dimmable smart lights in the office (SmartLights).

#### Training Sequence

The user enters their office at 2:30:00 PM on Wednesday afternoon. PIROffice sends a motion detected message to the hub. The hub logs that PIROffice detected motion at 2:30:00 PM. It is a sunny afternoon, so the home owner does not turn on the lights. The owner continues working uninterrupted until 7:45:00 PM, when the sun begins to set. The hub logs that LightOffice is reading a lower value due to the drop in light in the office. The owner turns the lights on dimly, to maintain the previous light level of the room, causing the hub to log that SmartLights turned on. As the light level of the room continues to drop in the room, the owner continues to raise the brightness of the lights. The hub continues to log this interaction. Eventually, it is dark outside and the lights are at full brightness in the room.

When the owner is done working, they get up, turn off the lights, and leave the room. The hub logs that PIROffice detected motion at 9:00:00, and logs that SmartLights turned off at 9:00:03.

#### Alternate Sequences

The light level of a room will not always be the same at a given time of day. The owner could enter their office at 2:30:00 PM on Wednesday afternoon, and turn the lights on immediately because it is rainy outside. The hub would log motion detected by PIROffice at 2:30:00, and then the value of LightOffice increasing to the desired value immediately following. This sequence would end the same way as the primary training sequence.

### Expected Inputs

The logs for the training scenario would look like the following: PIROffice = 0 when there is no motion detected, 1 when it is detecting motion

```
Initial Sensor States
LightOffice: 10
SmartLights: 0
PIROffice: 0
```

```

2016-11-06 14:30:00 [Sensor Update] PIROffice: 1
2016-11-06 19:39:00 [Sensor Update] LightOffice: 9
2016-11-06 19:42:00 [Sensor Update] LightOffice: 8
2016-11-06 19:45:00 [Sensor Update] LightOffice: 7
2016-11-06 19:45:10 [User Action] SmartLights: 3
2016-11-06 19:45:12 [Sensor Update] LightOffice: 10
2016-11-06 19:48:00 [Sensor Update] LightOffice: 9
2016-11-06 19:51:00 [Sensor Update] LightOffice: 8

2016-11-06 20:01:00 [Sensor Update] LightOffice: 8
2016-11-06 20:05:00 [Sensor Update] LightOffice: 7
2016-11-06 20:05:10 [User Action] SmartLights: 10
2016-11-06 20:05:12 [Sensor Update] LightOffice: 10
2016-11-06 21:00:00 [Sensor Update] PIROffice: 1
2016-11-06 21:00:07 [User Action] SmartLights: 0
2016-11-06 21:00:08 [Sensor Update] LightOffice: 0

```

The alternate sequence could look like this:

```

Initial Sensor States
LightOffice: 0
SmartLights: 0
PIROffice: 0

```

```

2016-11-06 14:30:00 [Sensor Update] PIROffice: 1
2016-11-06 14:30:03 [User Action] SmartLights: 10
2016-11-06 14:30:06 [Sensor Update] LightOffice: 10
2016-11-06 21:00:00 [Sensor Update] PIROffice: 1
2016-11-06 21:00:07 [User Action] SmartLights: 0
2016-11-06 21:00:08 [Sensor Update] LightOffice: 0

```

### Expected Behaviour

From the logs the Aria system should be able to tell that the desired light level of the owners office when occupied is 10. The system should automatically adjust the brightness level of the Smart Lights to achieve this level of brightness while the home owner is in the office. Upon the owner leaving the office, the system should recognize that the lights must be turned off.

### Sensor and Device Correlation

The graphs below depict the relationships between the light sensor, the motion sensor, and the smart light brightness level in multiple different scenarios. The goal of these graphs is to illustrate how the machine learning can interpret the sensor data to achieve the required functionality. The first relationship that the machine learning will need to recognize is the correlation between the PIR detecting motion and the lights being turned on. When no motion is detected, the light level detected by the LightOffice sensor is allowed to decrease to 0 without the lights being turned on.

Now that the system understands the relationship between no motion being detected and lights staying off, it needs to determine when it is appropriate to turn lights on when motion is detected. This is the relationship between the LightOffice sensor and the SmartLights brightness level. The first time the SmartLights are turned on by the homeowner is when the level of light detected by the LightOffice sensor falls below a certain level. The lights are turned on enough to maintain the level of brightness observed before it started decreasing. As the light levels continue to drop, the SmartLights brightness continues to rise in compensation. The threshold use to determine when the lights turn on is something that will be determined by how dark the homeowner allows the room to get before turning on the lights when training. The falling-rising pattern of the light level concludes when the SmartLights are at maximum brightness or when the light sensor is at a consistent level.

The final decision the system has to make is when it is appropriate to turn off the office lights. In the training scenario, the home owner turns the light off when leaving the room. The motion sensor stops being triggered around the same time that motion is no longer being detected. This has the potential to raise issues for the learning. For example, if the home owner is stationary for a short period of time in the room, the lights should not turn off. As well, if a new person enters the room and then leaves shortly after, the lights should not turn off. This is why the "Time Since Last Motion" (TSLM) variable is present. It is simply a timer that resets any time the motion sensor detects motion. Having this variable allows the absence of motion to be a value that is submitted to the machine learning algorithm. When the system is performing this scenario, the lights will likely remain on for a period of time

after the homeowner leaves the room until the TSLM variable reaches a certain threshold. This threshold will be dependent on the sensitivity of the motion sensor. The more sensitive the sensor is to motion, the smaller the threshold will be. The reason for this is that if the sensor can detect motion such as the homeowners head moving while they are sitting at a computer typing, it will be easier to determine that they are still in the room. If the sensor is only able to notice large movement, this has the potential to lead to an inconvenience to the user in the form of the lights turning off while they are still present in the room. They would need to make a big enough motion to trigger the motion sensor, thereby turning on the lights and resetting the TSLM variable.

## Graphs

## Feature Extraction

- Time Since Last Motion

The length of time since motion had been last detected by the PIR. If no motion is detected for a long period of time, then the learning could interpret it as there being no occupancy in the room. This could be determined by using a counter on an interval. Whenever a message is received, this counter would be reset. If the counter reaches a certain amount of time then a message is logged saying no motion is detected. This feature alone is not sufficient to determine if there is a person in the room, as they could remain still for a long amount of time. Knowing the occupancy of the room would solve this issue.

- Occupancy of the Room

Having a system know the occupancy of a room is not a trivial task, and is one that this scenario is not currently equipped to be able to do. A possible solution would be to have a double break beam on a doorway. While not perfect, this would provide a reasonably accurate count of people entering and leaving a room. The occupancy of a room can be extracted from this data.

- Light Level Trend

Light sensors are generally noisy and will provide many samples over a short period of time. In order to have a more accurate representation of the state of the light in the room, the sensor reading's could be averaged to get a general state. This average value can then be compared to previous averages of the lights value to get the trend of the light in the room. This can be used to indicate if the light in the room is increasing or decreasing.

- Time of Day

The time of day will be relevant when determining the light information as it can help indicate the daylight available. It is likely that at the same time each day, the lights will be in the same state as the day before. Using the time of day can provide a good indication of the light levels that will be desired in the room.

## Lighting Scenario Data

The purpose of this section is to present analysis of actual device data for the Smart Lighting Scenario.

### Devices

- Aeon Labs Z-wave Multisensor 6
- LB60Z-1 Z-wave Dimmable lightbulb

### Steps to Produce

1. Motion sensor and Dimmable LED set up facing each other in empty room.
2. User enters the room
3. User turns LED on to 100% brightness
4. User decreases LED brightness to low value
5. User blocks multisensor with hand
6. User increases brightness level to 100%
7. User turns off LED from Web UI and leaves the room

### Data

```
SELECT event_id,
       e.timestamp,
       e.source,
       p.NAME,

## H System Design

---

### H-1 Hub Implementation

The RequestTracker listens to the Exchange and decorates the DatabaseTranslator, filtering out all requests that have the Hub as the destination. These can be ignored because these request are for getting information about the system and don't need to be stored for machine learning. The RequestTracker also associates a request with an event so that any changes the request made can be tracked. If a device that can be controlled sends an event and there is there was no request to that device a request is created by the request tracker in order for the user action to be tracked.

## **Retriever**

The Retriever class is used to query the database and retrieve events. Currently it is possible to query for a list of all events or a list of all events for a specified device.

## **Delegate**

The delegate interface is an Observer interface. The interface implements two methods; received and discovered.

## **Device**

A device is a representation of a device that is connected to the system and can provide input or be controlled.

## **DeviceType**

The Device type represents the different types of devices that are in the system. The device type contains information about the manufacturer of the device the protocol the device speaks and the different attributes that the device has.

## **Attribute**

Attributes represent the different attributes of a device that can be viewed and/or changed

## **DataType**

Data type is an enum that is used to represent the data types of device attributes. The possible values of this enum are:

- 'binary'
- 'int'
- 'float'
- 'colour'
- 'enum'
- 'time'
- 'date'
- 'string'
- 'list'

## **CLI**

The CLI provides a command line interface for the user to issue command directly to the hub. Current commands are:

- help
- exit

## **Hub**

The Hub is a device that contains the current system state. The Hub has a list of all of the devices in the system, what mode the system is currently in and is able to query the database to get events.

## **Exchange**

The Exchange is used to route messages through the system. The exchange listens to all of the adapters and receives all the messages that are passed through the system.

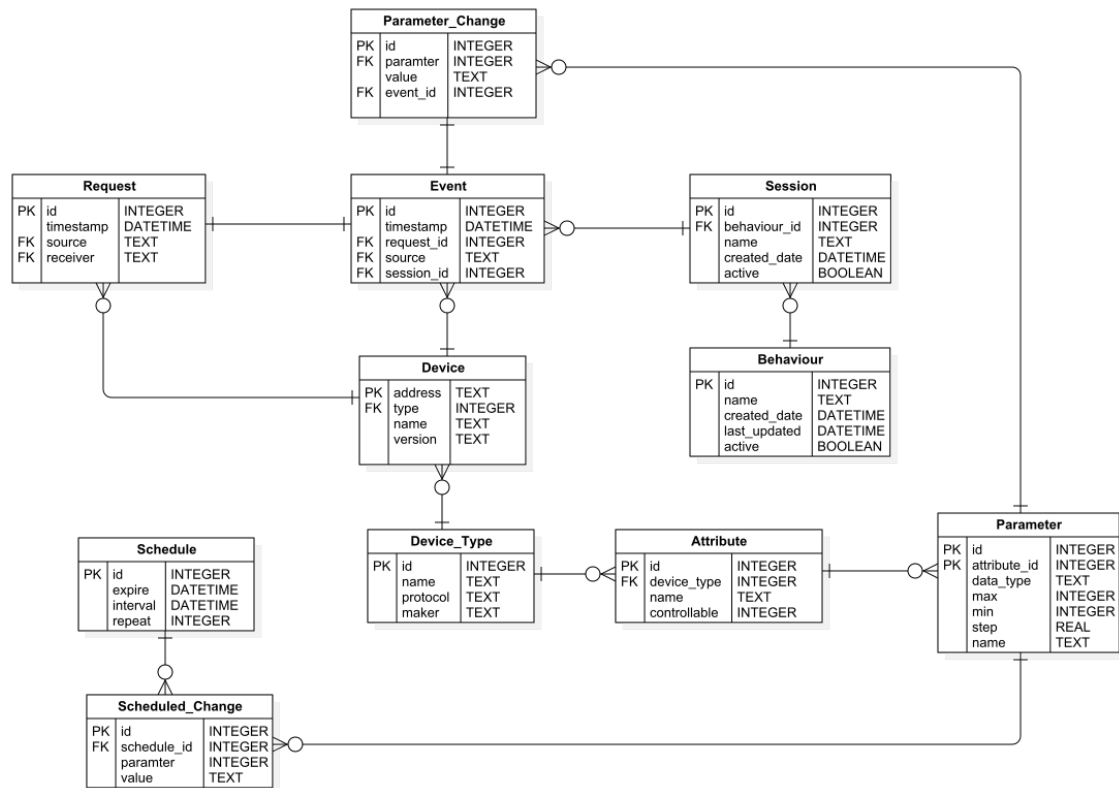

## **HubMode**

HubMode is an enum that contains the fdifferent modes of operation of the hub. The following are the possible values:

- StandBy
- Normal
- Learning

## H-2 Database

### Database Entity-Relationship

### Database Tables

#### Request

A request generated for a device. This request can be generated from the UI, the machine learning, or by an external user on the physical device. A row in the Request table is a requested state change of a controllable device.

#### Event

An event generated for the system. An event is a response to a request, changing the value of a device attribute based on the request. Events are linked to the Requests that cause them through the request\_id foreign key. They are also linked to devices through the source foreign key, which is the device which caused the event. An event can also be generated by a non controllable sensor, in which case it will not be linked to a Request. If an event occurs during a training session, that session id stored with the event.

#### Parameter\_Change

Holds the requested parameter to change or the parameter changed by an event, linked to by a foreign key in the Request and Device tables. The parameter field is a foreign to the Parameter table.

#### Session

Represents a single training session within a desired learned behaviour. A session is linked to one behaviour, has a name which is set by the user, has the date it was created, and can be toggled on or off. Once the user begins a new training session, any event which occurs until the session is stopped will be linked to that session.

#### Behaviour

Represents one desired learned behaviour of the system. The user creates a behaviour with a name, and can then add training sessions to this behaviour. The date of creation and the date of the last update to the behavior are also stored. Similar to a session, an entire behaviour can be enabled or disabled.

## **Device**

The individual devices connected to the system. Each device is uniquely identified by its UUID, stored as the address. Each device has a device type, which can be used to determine what attributes are available for a device of that type.

## **Device\_Type**

Specific manufacturer information for different types of possible devices (WeMo switch, Hue lights, etc...). This table also holds what communication protocol is needed to communicate with a device type and if it is an input or not.

## **Attribute**

An attribute is a field of a device that provides information about the current device state. A controllable attribute is one such as the colour of a smart light bulb, where as a non-controllable attribute would be one such as reading from a sensor. Attributes can have multiple parameters associated to them. Take a smart light bulb for example; the attribute would be the colour of the bulb, and the parameters could involve different possible colours such as red, blue, and blue.

## **Parameter**

Parameters are associated to an attribute. They are used to describe the possible states of their associated attribute.

## **Schedule\_Change**

Used to enable device scheduling. A parameter is associated with a value to change to, and a link to the schedule table. This link is used to determine when the requested parameter change should occur.

## **Schedule**

A schedule determines when a parameter should change. It allows for a scheduled event to be recurring according to date, repeated for a set number of times, or simply occur once.

# **H-3 Requests**

## **Introduction**

The purpose of this section is to provide an understanding of the interactions between an end user and the system for different types of requests.

## **Web Client**

### **User**

The User actor represents an end user of the system, which is the Web Client in this case. The user initiates all requests in the use case diagram for this system.

### **System Hub**

The SystemHub actor represents the central hub of the Aria system. The system hub is in charge of relaying information of the system to the User through the Web Client.

## **Device**

The Device actor represents any device in the Aria system. A device is responsible for relaying its specific information to the User through the Web Client.

## **List Devices**

Return a list of all devices currently known by the system to the User.

## **View System Events**

Return a log of recent events that have occurred in the system. An event is when the state of a device changes.

## **Get System Status**

Return the status of the system to the user. This includes information such as what mode is the system currently operating in, current version number, number of connected devices, etc.

## Set System Mode

Set the mode of the system. The different modes are: Standby(0x00), Normal(0x01), and Learning(0x02)

## Add New Device

Add a new device to the system. This allows the end user to connect a new device to be controlled by the system and contribute to the machine learning.

## Remove Device

Remove a device from the system. This allows a user to remove a device and its information, no longer allowing it to be controlled by the system. If added back to the system, there will be no stored information on it.

## Get Device State

Return the current state of a device to a user. The state information could include if it is on, off, and other values depending on the device.

## Set Device State

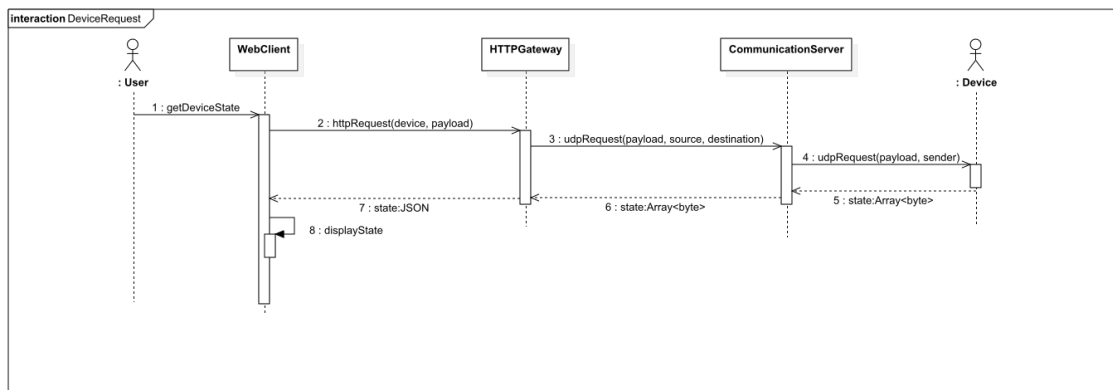

Set the current state of a device. The state information could include if it is on, off, and other values depending on the device.

## Server Request

The Server Request diagram shows the workflow that occurs when an end user wants to retrieve information about the state of the communication server through the web client.

## Device Request

The Device Request diagram shows the workflow that occurs when an end user wants to retrieve inform about a specific device in the system through the web client.

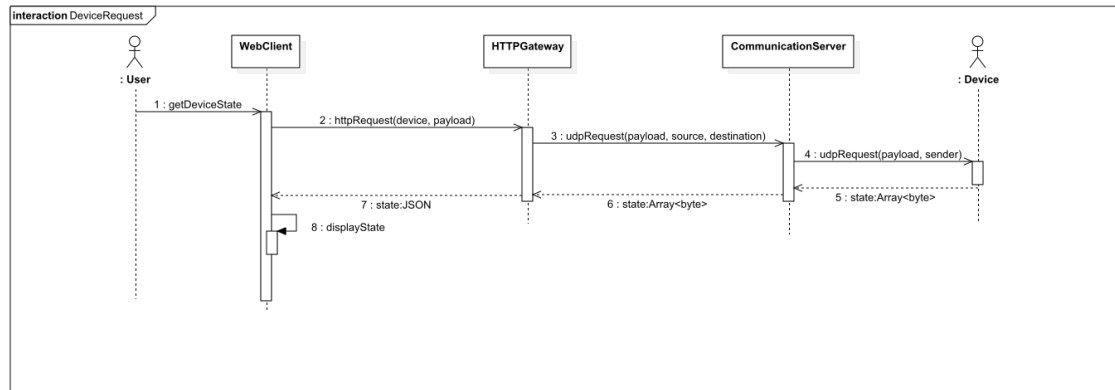

## H-4 Discovery

### Overview

In order to add a device to the central exchange hub registry, the device must be added through the discovery sequence. Until the device has been added, no communication can take place. Device discovery can be initiated from external devices or from the hub itself. This section outlines the discovery sequence in both scenarios.

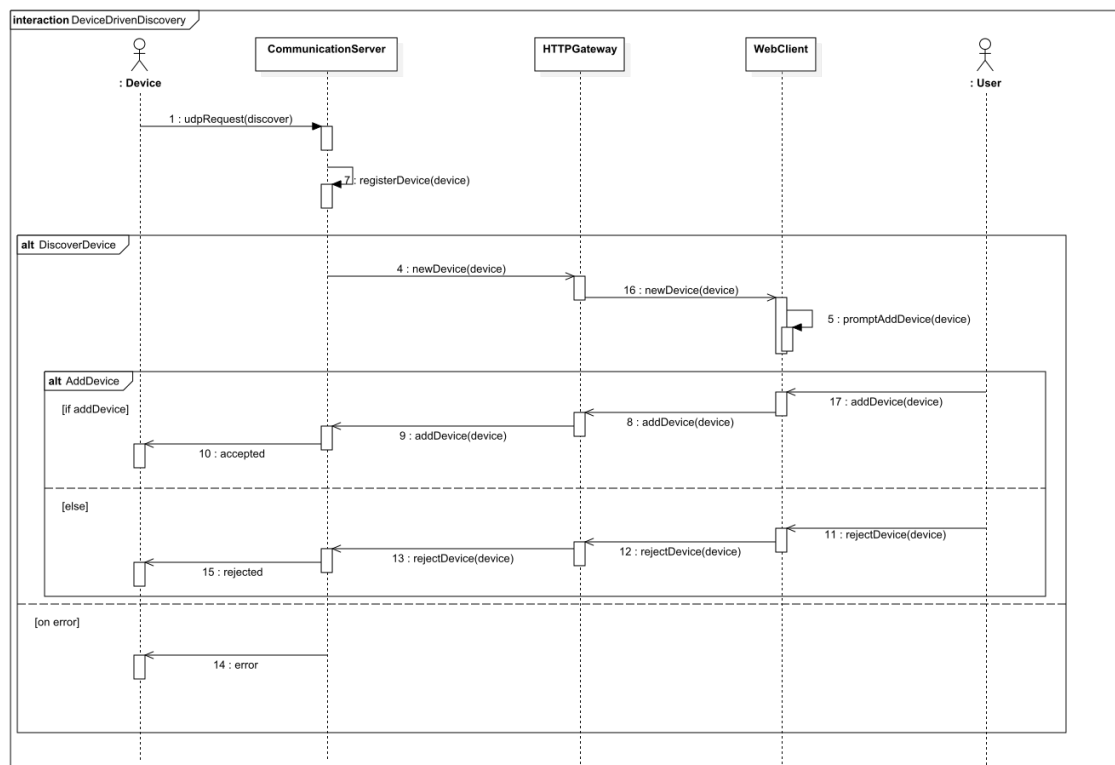

### User Driven Discovery

User initiated discovery begins with the user requesting the server to send a discovery request. The message then propagates through the system to the communication server which sends a broadcast discovery message to find new devices. If a device receives a request to be discovered then it begins the device driven discovery sequence

### Device Driven Discovery

Device initiated discovery begins with an initial discovery request sent from the device. The hub will receive a request for the discovery with device details. If the device has valid information then the request is propagated to the web client. Once the web client receives a notification that a new device is available, it prompts to user to add the device. The user can then choose to accept or reject the device which will send a message to the device.

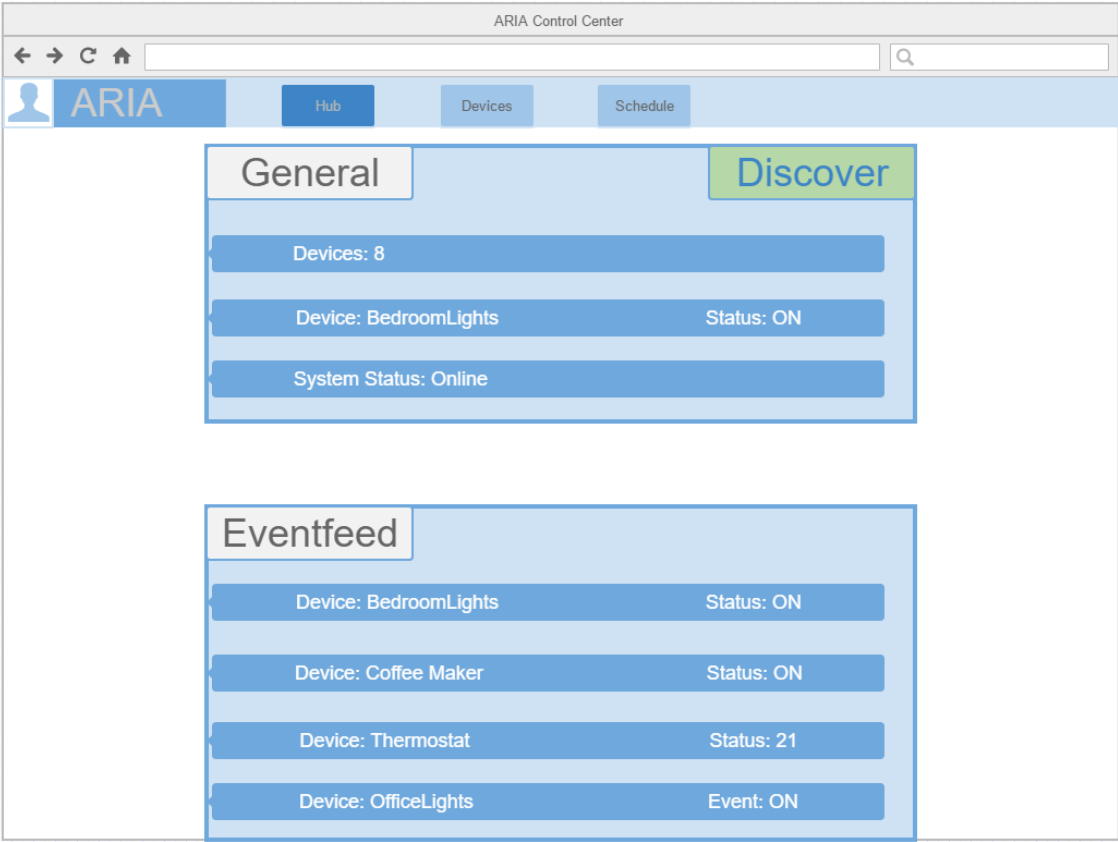

## H-5 Remote User Interface

The user interface must be able to provide the user with control of the Aria system. It must provide features for observability and controllability of the system. This interface is the sole point of communication of the user to the system so it needs to be presented in a non-technical way that provides complete control.

In order to be accessible from any computer, the remote interface will be served as a web application to any standard browser. The user can log into their favourite browser and navigate to the remote application by typing in the address of their smart hub

### Home Page

When the user initially logs into the smart hub page, they will be presented with the remote home screen. The starting page of the remote provides a general overview of the state of the system as well as an event feed of the latest device interactions. The user can use this page to change the system's state from standby to training or normal mode. For convenience, the user can jump right to device discovery and being configuring a new device in the system by clicking the "Discover" shortcut. Below is an outline of what the remote home page could look like.

### Devices

In order to go into more details about each device, the user will also have a devices page. The devices page allows a user to control or configure a given device. The user can choose to perform a specific action by clicking the UI toggles for the appropriate task. Interacting with the UI in this manor to cause an event will be logged in the system in the same way as it would if the user had manually interacted.

Each device can also be scheduled to perform specific tasks at desired times. This can be done by pressing the schedule tab, adding an action and configuring the date and time. These scheduled tasks will override any smart hub decisions and will be top priority. Below is an outline of what the devices tab could look like.

## Statistics

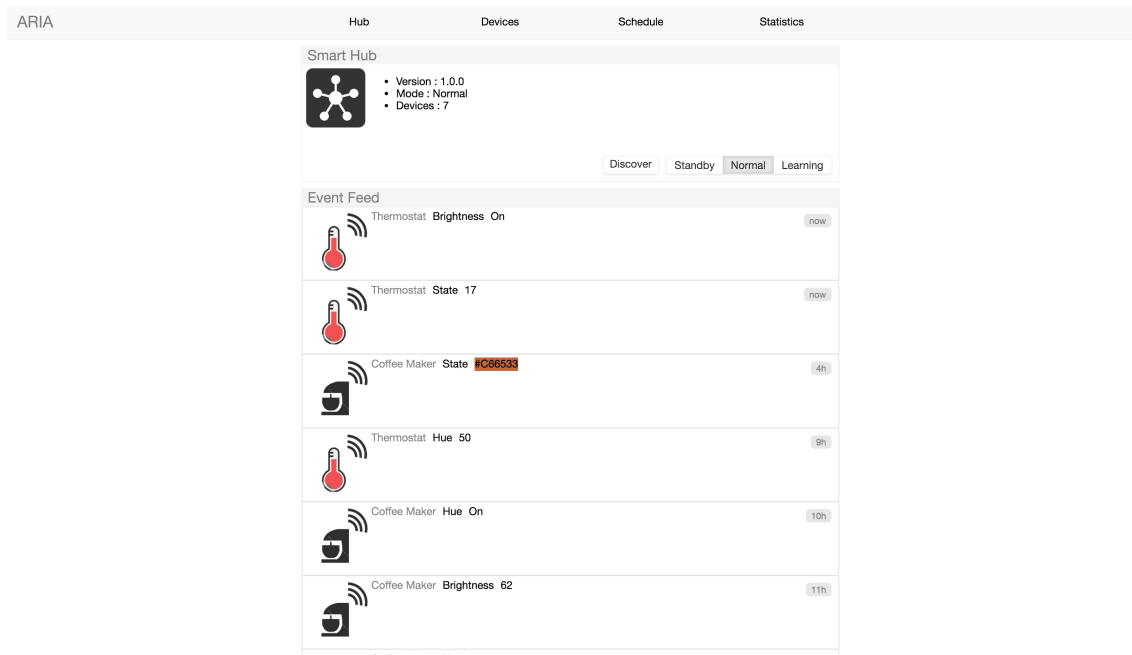

To aid in observability of the system, a statistics page will be provided. This page will allow the user to view all of the data logs that are contained within the system as well as plot them using various regressions through the UI. The plots created through the UI will help the user in understanding the decisions that the system makes by displaying its data in easily consumable graphs.

## H-6 Remote Implementation

The remote client provides a user interface for the end user to control and observe the state of the system. It is responsible for providing events and notifications to the user about the current operations of the hub and its devices. The remote must also provide controls for changing the state of all components within the system.

## User Interface

### Hub Page

This page provides the user with controls for updating the state of the hub and discovering devices. In the lower area of the page there is an event feed that is updated using push notifications whenever an action happens within the system. This provides the user with details about the behaviours in the system, what is changing and when it happened. To notify the user when errors or warning happen within the hub, push notifications are used.

Discovery

When the user presses the discover button, the system begins a device discovery sequence. It begins searching for new devices in the local network area. If a device is found by the hub then it is added to the hub. The user is notified of the addition of these devices through push events as seen below.

Device Page

ARIA	Hub	Devices	Schedule	Statistics
Light				
		Name: Light Manufacturer: Aeon Labs Protocol: SmartThings	Brightness 76	
Light				
		Name: Light Manufacturer: Google Protocol: ZigBee	State 19	
Thermostat				
		Name: Thermostat Manufacturer: WeMo Protocol: SmartThings	State 37	
Coffee Maker				
		Name: Coffee Maker Manufacturer: Aeon Labs Protocol: UPnP	Hue	
Coffee Maker				
		Name: Coffee Maker Manufacturer: Aeon Labs	Brightness 66	

This page is responsible for providing the user with state information and controls for the devices within the system. Each device's current state is displayed to the user in the device list. Currently, there are no controls for a device but they will be implemented using the wire frame as discussed in the [remote user interface design](#)

Implementation

The remote client is designed entirely using HTML, JavaScript and CSS. For more information about the technologies used, see [web client technology](#).

All of the client code follows a *reactive* pattern where all views update as state changes. All view components in the system follow the composition pattern and inherit from a common component class. Whenever state changes, each component follows a transition pattern to redraw itself with the new state. First, the state of the component is *updated* which in turn updates all of its child components. Next, the interface is re-rendered. This is done by calling *render* on the top level component that has changed. When a component is rendered it is responsible for calling *render* on all of its children creating a trickle effect. Through this method, calling *render* on the top level component will re-render all of the changed elements.

## H-7 Gateway Implementation

### Exchange Adapter

The exchange adapter is responsible for communicating with the exchange server using inter process communication with a connectionless socket. When the exchange adapter registers itself with the exchange server it provides a callback port for asynchronous callback events. This allows the exchange server to push communication to the gateway, which in turn forwards them on to the remote client.

### Test Adapter

The test adapter allows the server to run independently of the exchange server and rely only on integration tests. The integration tests provide a complete mock of the IPC protocol so that all exchange communication is controlled. This is used for testing the gateway and remote client in isolation from the exchange server.

### Server

The server class is the main class for the gateway project. This class initializes the appropriate adapter object for the gateway class and binds itself to a port for serving data.

### Gateway

The gateway class provides a REST interface for communicating to the system over HTTP. The gateway delegates the endpoints of the REST API to various routers. Internally, this is done using the strategy pattern. As a request enters the system, it is routed to the appropriate handler based on its URL.

### HubRouter

The hub router handles all requests for the hub endpoint. This router deals with communication that will request or update the state of the central hub. The hub router is also responsible for retrieving event logs from the hub's database.

### DeviceRouter

The device router handles all individual device requests. It is responsible for updating individual device states as well as querying all device data.

## IPC

The IPC class is responsible for communicating to the exchange server. It serializes and deserializes messages using the defined IPC protocol ([see IPC](#)).

## H-8 Communication with Z-Wave Devices

The system uses the Aeotec Z-Stick Series 2 from Aeon Labs to communicate with Z-Wave devices from the system's hub. The Z-Stick is attached to a USB port in the system hub device (Raspberry Pi).

### Controlling the Z-Stick

When connected to a USB port, the Z-Stick exposes a proprietary serial API, which can be used by controller software to manage a network of Z-Wave devices. This document describes how the hub software uses the Z-Stick to communicate with devices in the home's network.

### Z-Stick API

There are several challenges to overcome in order to write Z-Wave controller software that uses the Z-Stick.

- Proprietary API: The serial API exposed by the Z-Stick is not made public
- Low-level: The Z-Stick API is very low-level; significant effort is required in order to use the most basic features of Z-Wave devices

In order to avoid the difficulties of using the Z-Stick API directly, we chose to search for a Z-Wave controller library which provides a higher level of abstraction away from the Z-Stick API.

### Library Alternatives

Comparison Criteria

- Does the library have a Python binding? The hub code is primarily written in Python, it is less effort to include a Python library as opposed to a C/C++ library
- Is the library mature enough to be a reliable part of the project? If many other projects use the library already, with positive results, this indicates that the library is stable enough to include in the project
- Is documentation and tutorial material readily accessible?

### Sigma Designs Developer Kit (ZWare)

Sigma Designs is the primary company involved in development of the Z-Wave protocol. Sigma Designs provides an developer kit, targeted at companies that are attempting to build custom Z-Wave devices. The targeted applications for the library are listed as: door locks, lights, sensors, and thermostats.

For commercial applications, the developer kit also includes licenses which allow custom Z-Wave devices to be sold legally [66].

The developer kit provides access to the following software resources:

- Documentation for the Serial API
- Z-Ware C API
- Sample applications

### OpenZWave

OpenZWave is a free open-source library for communicating with Z-Wave devices using compatible ZWave controller devices. The Aeotec Z-Stick is fully compatible with OpenZWave. OpenZWave is a C++ library; the developers have created bindings for several other languages including Python.

The OpenZWave source code is well-documented, and includes several examples of usage. OpenZWave is used by several existing home automation products to communicate with devices, with 259 forks on Github and an active community of developers [67]. Additionally, OpenZWave is a member of the Z-Wave Alliance, the consortium of companies that certifies Z-Wave devices [68].

### Comparison

Library	Python Binding	Maturity	Availability
Sigma Designs	No binding	Official SDK	License Required
OpenZWave	Has a binding	Mature	Open Source

We decided to include the OpenZWave library in the project. The availability of a Python binding for the library makes including it in the project simpler than the Sigma Designs C API. The Sigma Designs Developer Kit is also targeted at companies that are attempting to create their own certified Z-Wave devices, which is outside the scope of this project. Tutorials and examples of using the OpenZWave library are also more accessible online, from a variety of sources.

## H-9 Data Flows

### 5.0.0.1 Add Device Data Flow

This data flow outlines the details of how a new device is connected to the system. In particular, this workflow focuses on adding a Z-Wave device to the system after. This workflow assumes that the system is already online and operational, that the Z-Wave stick is plugged into the smart hub and that the network is live

When the Z-Wave adapter starts up, it uses the OpenZWave library to initiate a Z-Wave network. When a Z-Wave device is first paired with the Z-Stick (which is attached to the Raspberry Pi), the network initiated by our Z-Wave adapter receives a device object. This device object has been built by the OpenZWave library. An example of a such an object is shown below. For all of the data received from the device see [Appendix-G](#)

```

basic:4
product_name:LB60Z-1 Dimmable LED Light Bulb
device_type:Light Dimmer Switch
values:{
  72057594093076481:{
    'label':'Level',
    'data':99,
    'genre':'User',
    'value_id':72057594093076481,
    'units':'',
    'node_id':3
  }
}
  
```

```

    },
    72057594093076504:{
      'label':'Bright',
      'data':False,
      'genre':'User',
      'value_id':72057594093076504,
      'units':'',
      'node_id':3
    },
    72057594093076520:{
      'label':'Dim',
      'data':False,
      'genre':'User',
      'value_id':72057594093076520,
      'units':'',
      'node_id':3
    },
  },
  node_id:3
  location:
  name:
  product_name:LB60Z-1 Dimmable LED Light Bulb
  type:Light Dimmer Switch
  manufacturer_name:Linear
  name:
  home_id:4036346586

```

Once this ZWave object is received by the adapter, it is converted into a generic device object which can be used internally in our system, shown below. We also set the location on the ZWave device to a UUID we have generated so that we are able to track this device if it is ever disconnected from the system.

```

name: LB60Z-1 Dimmable LED Light Bulb
DeviceType: {
  LB60Z-1 Dimmable LED Light Bulb
  protocol: zwave,
  maker: Linear
  Attributes:
  [
    {
      name: Bright,
      parameters: [
        {
          name: Bright,
          DataType: binary,
          value: False,
          min 0,
          max: 0,
          step: None
        }
      ]
    },
    {
      name: Level
      parameters: [
        {
          name: Level,
          DataType: byte,
          value: 99,
          min 0,
          max: 99,
          step: None
        }
      ]
    },
    {
      name: Dim,
      parameters: [
        {
          name: Dim,
          DataType: binary,

```

```

        value: False,
        min: 0,
        max: 0,
        step: None
    }
}
]
}
}
address: abb757fc-5d38-45c8-bbbc-81cf6bf29d92
version: 4

```

Our ZWave adapter now notifies the Exchange that a device has been discovered, passing it the new device object. From here, the device must be stored in the database, and the UI needs to be updated to display the new device and its information. The exchange forwards the device object to the database and to another adapter, which formats it properly for the UI.

The device adapter is responsible for doing this formatting. In order to be properly displayed on the UI, the device object must be converted into a JSON string. Once this is done, a device discovered message is sent to the Gateway.

The purpose of the Gateway is to take messages received over a UDP socket and forward them over a Web socket to the user interface.

## I Development Lifecycle

---

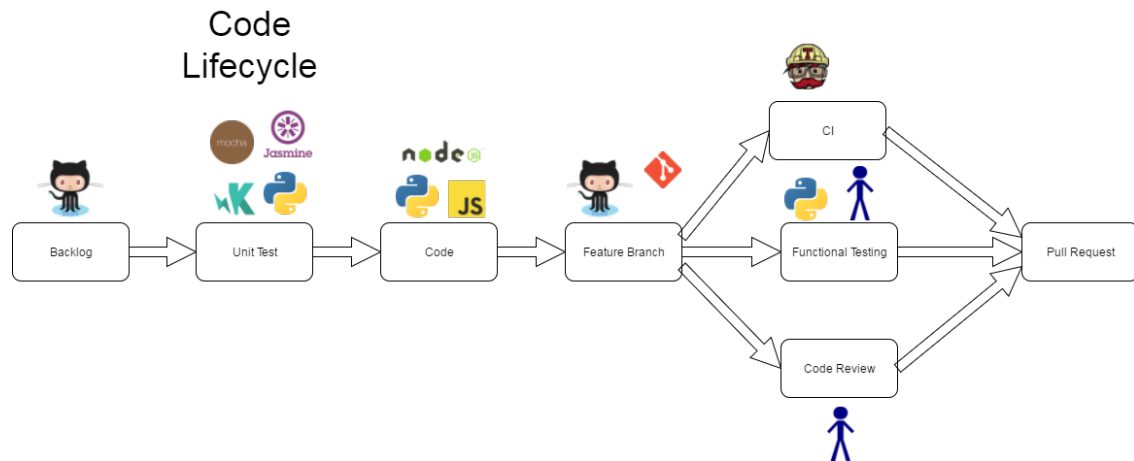

### I-1 Development Process

#### Introduction

An important part of any sizeable software project is the selection of an appropriate development process. A development process imposes a particular structure on the development of a product. The process used for the development of this project was created with the following factors in mind:

- Project lifespan: Work on the project will last at least 8 months; other developers may also continue working on the project after the two school terms are complete
- Team Size: There are four team members working on the project, the process needs to keep everyone synchronized and organize the assignment of work to team members
- Reporting: The final project report is critical to the project's success, the process should make the report easier to write in a consistent manner
- Code Quality: The process should ensure that work products are of the quality expected of a fourth year project.
- Maintainability and Extensibility: The end result of the project should be maintainable and extensible; a developer who is new to the project should have an easy time developing for it.
- Ease of Implementation: The process should not be an obstacle to development

Given these goals, the process used for this project incorporates some elements of Extreme Programming and other Agile methodologies. Use of practices which are widely accepted in industry also ensures that new developers are comfortable working on the project. The process prescribes some practices to be used for: Source Code Management, Code Reviews, Issue Tracking, and Testing.

### Source Code Management

The project uses a source code management tool to achieve the following goals:

- Allows many team members to work on the same codebase and maintain a consistent master copy of the project
- Track changes to files in order to locate changes that may have introduced bugs
- Allows team members to work independently and simultaneously

This project uses git because it provides solutions to all of these issues. Git is familiar to all team members, in addition to being a de-facto standard in the open source software community. Using git over other SCM tools makes the process easier to follow, and improves the experience of any new developer that might choose to maintain the project.

The project's git repository is hosted on Github. Github allows the team to access the project anywhere, and makes sharing code with new developers simple. Additionally, Github provides some project management tools that can be used elsewhere in the process, as explained in subsequent sections.

### Branching and Code Reviews

We make strategic use of a git feature, branching, in order to ensure that code which makes it into the official version of our software is of the quality expected of a fourth year project. A technique we are using to ensure code quality is peer code review. By frequently reviewing code, we can share knowledge between team members with different amounts of experience in particular technologies.

In order for code reviews to be effective, we believe that the review should be as short as possible, and focused on a particular feature. This ensures that reviewers are motivated to provide high quality feedback. In order to encourage this, we have adopted the "feature branches" branching strategy. Work on a particular feature is submitted to its own branch; branches are merged to master once work on the feature has been completed. A code review is required before any branch may be merged into master. Feature branches helps to ensure that code reviews are short and focused.

### Continuous Integration

A practice which complements the branching strategy adopted by this project is continuous integration. In combination with test automation, continuous integration allows team members to get early feedback about changes they make to the codebase. Proper use of continuous integration can ensure that the project's master copy remains in a working state at all times. One of the benefits of maintaining working software at all times is that the project is always demo-able.

The continuous integration tool chosen for this project is Travis CI. Travis CI is a free hosted CI system. Travis can be easily integrated with Github repositories, and provides quick and reliable feedback about the build state of the system.

Github rules were created to ensure that any code which is merged into the master branch does not break existing work. Merges to master are blocked until Travis has successfully run unit tests on the merged code.

### Issue Tracking

In order for the team to measure the progress of the project, and to ensure that tasks are not forgotten, it is important for this process to incorporate a process for tracking tasks. Issue tracking may also simplify the task of writing the final report by providing a list of the tasks completed during the project.

Another advantage of issue tracking is that team members can be explicitly assigned to specific issues to work on; this ensures that efforts are not duplicated.

A good issue tracking tool:

- Provides a visible list of things to do
- Allows tasks to be ordered so that team members know what to do next
- Provides a forum for discussion of tasks

Github provides an issue tracking system which can be used to accomplish these goals. The Github issue tracking system is not ideal for some tasks, such as prioritization of issues. In the interest of minimizing the number of tools required to follow this process, however, Github issue tracking was selected as the team's issue tracking tool.

Github issues are organized into groups of tasks which must be completed during each one-week iteration of development. Issues are prioritized using labels (minor, major, critical, blocker). Issues are assigned to a team member when work begins; when work on an issue is completed the issue is closed using a commit message.

#### 5.0.0.2 Workload Estimation

During each weekly sprint, the team selects a number of tasks to commit to finishing during the week. In order to attempt to avoid committing to too much work during a sprint, the effort required for each task is estimated relative to a well-known issue. When the time comes to bring these tasks into a sprint, each size is given a number of story points based on the estimated effort. Story points are simply a number which reflects the difficulty of the task relative to the baseline. The number of story points allowed in a sprint is based on the historical number of story points that the team has completed, and adjusted for the estimated availability of team members. This process helps prevent the team from taking on more work than can be reasonably accomplished.

#### Testing Practices

Agile processes generally encourage a short feedback loop for developers (problems with code should be exposed as early as possible). This project uses principles of test-driven development (TDD) and behaviour-driven development (BDD) in order to ensure that development remains focused on problems which are relevant to the end user. Any change to the code should be accompanied by an automated test or set of tests which exercises **end user functionality**. That is, automated tests should function as an executable specification of requirements for the unit under test.

## I-2 Deployment

### Introduction

This section outlines the details about building and deploying the Aria system. It details how the system's automated build process executes and the build manifest. This document also outlines the major decisions that were made to run the build and the reasoning behind them.

### Build Process

The build process uses a centralized manifest structure to execute the build. The build system does not use a build automation suite but instead integrates a number of different technologies for deployment. The executing process that runs the build is a simple shell command executor that runs over a set of commands from a central manifest.

The central manifest contains all of the build commands for each sub-project. It is a collection of bash commands that are executed in order to build the system. This manifest file is located under the build directory and is named `manifest.json`.

The Aria system is composed of many subsystems that each require their own build tool chain. Each subcomponent has its own set of build commands which are encapsulated within the central manifest. For this reason, it was decided that a simple command executor would be more suitable for running the main build process rather than having another architecture to try to execute the commands.

The deployment of the Aria system is not restricted to a single platform but is instead intended to operate on many different operating systems with many different package managers. To accommodate this requirement, a package manager wrapper was built. This wrapper dispatches commands to the appropriate system package manager to download any required dependencies for this project. This is used in conjunction with the main build system, allowing the Aria system to be deployable on numerous architectures.

### Package Management

Almost every system has a different set of package management tools. Most of these tools support the same features and can access the same packages for their specific system. To enable the Aria system to build on independent systems, a package manager wrapper named `pkman` was developed. This wrapper offers a standard set of package manager commands to install and uninstall packages using the target platform's specific package manager. This tool uses the facade design technique and allows the build process to use one generic interface to communicate to many different dependency management tools.

Since not all platforms offer the same set of packages, a special mode was added to `pkman` to support optional dependencies. Optional dependencies can be added by specifying a `--try` flag which indicates that if the package install does not succeed then continue without error. This is a major improvement that allows us to support packages which have different names per platform or even some that only exist on specific platforms.

**Building Aria**

The Aria system is built in several stages. These stages are executed in order to setup the target system's architecture for running Aria. Each stage is referred to as a directive in the build process. To perform a complete build these directives must be executed in order and then must be deployed.

**Executing a Build**

To execute a build in the aria system simple run the `./build/run all` command. This will execute all of the stages of the Aria build process including the Aria test suite. Once the build has been successfully built it can be deployed with the `./build/run deploy` command. This will start the Aria system processes in a daemonized state.

To execute a specific directive in the build, simply run the `./build/run` command with one of the following directives.

Directive	Description
<code>enviro</code>	Setup the target system's environment dependencies
<code>deps</code>	Install all of the target specific technologies
<code>build</code>	Build all of the targets on the build system
<code>test</code>	Execute the automated test suite on the build
<code>deploy</code>	Start running the Aria system
<code>clean</code>	Clean all of the build artifacts from the repository
<code>all</code>	Install all of the dependencies, build the system, and run the tests

## J Public API

**Introduction**

This section outlines the details of the application programming interfaces within the Aria system. It provides full specifications for all public interfaces that can be used to interact with the system.

**J-1 IPC Protocol**

This section defines a basic protocol for interprocess communication (IPC) between the HTTP gateway and the central server.

**Protocol Definition**

The messages defined by this protocol are sent using UDP.

The protocol uses a simple request-response format. The server listens for messages on port 7600. All request packets must be acknowledged by a response packet. This protocol is intended for IPC purposes, so it is anticipated that both the server and client are running on the same machine and packet loss is extremely unlikely.

In the event that no response is received within a reasonable amount of time, the request should be re-sent.

Messages follow the general message structure shown below. Messages are encoded as bytes, using Big-Endian byte order.

**General Message Structure**

+	-----+	-----+	-----+	-----+	-----+	+				
	type		size		sender	destination		payload		
+	-----+	-----+	-----+	-----+	-----+	+				
	1 byte		4 bytes		16 bytes		16 bytes		'size' bytes	
+	-----+	-----+	-----+	-----+	-----+	+				

## Message Types

The type field should contain one of the following values:

Name	Type	Value
Error	ERR	0x00
Discover	DISC	0x01
Request	REQ	0x02
Event	EVT	0x03
Response	RES	0x04

## Data Types

This section defines the data structure format of data structures used in the response to requests

### Data Type

Data type is an enum that is used to represent the data types of device attributes. Each data type has a unique set of behaviours and should be used appropriately. Each data type is configurable with three control parameters. The range of a data type can be controlled with a maximum ( `max` ) and minimum value ( `min` ). Some data types that do have a range of values should only increment in a specific sequence which can be controlled by the `step` parameter. The step of a value is the distance between two allowed values in a continuous range. It is a requirement that the step value is always a positive value and that the maximum value is greater than or equal to the minimum.

It should be noted that not all data types use these parameters. Some data types have pre-determined ranges or step values which are described for each data type below.

#### Binary

The `binary` type allows for control of a device from an 'On' and 'Off' state. These states are represented by 1 and 0 respectively. These are the only two values permitted by this data type.

#### Byte

The `byte` data type is an integer value with the range 0 to 255. This data type can be used to set a device in a specific mode or discrete value within this range. This data type ignores the max, min values of the data range as it is assumed the range is 0 to 255. The step value is respected by this data type but must be an integer value less than 255.

#### Integer

The `int` data type allows for a range of values from  $-2^{31}$  to  $2^{31} - 1$ . This is appropriate for values that need to be discrete but must satisfy a specific range. All of the data types are respected by this data type.

#### Float

The `float` data type allows for a continuous value input to a device. This data type is represented by an IEEE-754 floating point number and the associated range. The maximum and minimum values for this data type should be integer values. The step for this data type can be a float value that is less than the maximum float value.

#### Color

A `color` data type refers to an RGB value. The data type is encoded as a 4-byte integer value where each byte represents a RGB value. The last byte is currently not used but is reserved as an alpha value if the requirement arises. For example, the value for white ( `#FFFFFF` ) would be encoded as `0xFF 0xFF 0xFF 0x00` or 4294967040 decimal.

#### Enumeration

An `enum` data type is used to represent a set of pre-determine values in a group. The values of the enumeration must be encoded with the data type in a special `values` field which can be an array of strings representing the enumerated values. The `value` field associated with an enumeration field will represent the zero based index of the value in the values array.

#### Time

The `time` data type is a millisecond representation of a time interval. The value of this data type is a millisecond value as an integer. The maximum and minimum parameters to this data type will be used to limit the range of time available. The step can also

be used but must be an integer value.

#### Date

The `date` data type is a day representation of a time interval. The value of this data type is a day offset represented as an integer. All of the data type parameters can be used with this data type but they must be integer values.

#### String

The `string` data type is an open ended input which is represented by an arbitrary character sequence. The maximum and minimum parameters for this data type can be used to limit the length of the character sequence. The step parameter has no impact with this data type.

#### Attribute Parameter

Represents a parameter to an attribute of a device

```
{
  "name"      : <string>,
  "dataType"  : <DataType>,
  "max"       : <int>,
  "min"       : <int>,
  "step"      : <float>
  "enum"      : [<string>]
}
```

- **dataType**: a DataType from the above section
- **max**: the max value the attribute can be, this may be null
- **min**: the min value the attribute can be, this may be null
- **name**: the attribute name, this is used in set and get request to query the device
- **step**: the difference between each acceptable value of the device, may be null
- **enum**: a list of possible values for an enum

#### Attribute

Attributes represent the different attributes of a device that can be viewed and/or changed

```
{
  "name"          : <string>,
  "isControllable" : <boolean>,
  "parameters"    : [<AttributeParameter>]
}
```

- **name**: Name of the attribute
- **isControllable**: boolean value which specifies whether the device is to be interpreted as a sensor or an output device

#### Device Type

The Device type represents the different types of devices that are in the system. The device type contains information about the manufacturer of the device the protocol the device speaks and the different attributes that the device has.

```
{
  "attributes" : [<Attribute>],
  "maker"      : <string>,
  "name"       : <string>,
  "protocol"   : <string>
}
```

- **name**: the name of the type of device (WeMo Switch)
- **protocol**: specifies what adapter will be needed (Z-Wave, WeMo, etc)
- **maker**: device manufacturer name (Samsung, Aeon Labs, etc)

#### Device

A device is a representation of a device that is connected to the system and can provide input or be controlled

```
{
  "address"    : <string>,
  "deviceType" : <DeviceType>,
  "name"       : <string>,
  "version"    : <string>
}
```

- **address**: a unique UUID String used to identify a device
- **deviceType**: the DeviceType related to the device
- **name**: a user specified name for the device
- **version**: the device version number from the manufacturer

## Requests

This section defines the format of the request and response payloads that are understood by the central server.

## System Status

Title	<b>Get Hub Status</b> Return the hub status and any properties associated with the hub
Destination	The message must be addressed to the hub's well known ID: 00000000-0000-0000-0000-000000000000
Message	<pre>02 XX XX XX XX YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the sender's address</li> <li>• <b>PAYLOAD</b>: The body of the message <pre>{   "get" : "status" }</pre> </li> </ul>
Success Response	<p>Below is an example of a successful response.</p> <pre>04 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD</b>: The response to the status request <pre>{   "response" : "status",   "value" : {     "mode" : 1,     "name" : "Smart Hub",     "devices" : 5,     "version" : "0.2.3"   } }</pre> </li> </ul>
Error Response	<p>Errors are returned as an error packet of type 0x00</p> <pre>00 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD</b>: The response to the status request <pre>{   "error" : "Invalid request" }</pre> </li> </ul>

## Scan Devices

Title	<b>Start Device Discovery</b> Initiates a discovery sequence to find new devices on the network
Destination	The message must be addressed to the hub's well known ID: 00000000-0000-0000-0000-000000000000
Message	<pre>02 XX XX XX XX YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the sender's address</li> <li>• <b>PAYLOAD</b>: The body of the message <pre>{   "action" : "discover" }</pre> </li> </ul>
Success Response	Below is an example of a successful response. <pre>04 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD</b>: Message reports if discovery has started successfully <pre>{   "success" : true, }</pre> </li> </ul>
Error Response	Errors are returned as an error packet of type 0x00 <pre>00 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD</b>: The response to the status request <pre>{   "error" : "Discovery failed reason" }</pre> </li> </ul>

## List Devices

Title	<b>List Hub Devices</b> Returns the devices that are currently connected to the hub
Destination	The message must be addressed to the hub's well known ID: 00000000-0000-0000-0000-000000000000
Message	<pre>02 XX XX XX XX YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the sender's address</li> </ul>

	<ul style="list-style-type: none"> <li>• <b>PAYLOAD:</b> The body of the message</li> </ul> <pre>{   "get" : "devices" }</pre>
Success Response	<p>Below is an example of a successful response.</p> <pre>04 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX:</b> Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY:</b> Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD:</b> The response to the status request</li> </ul> <pre>{   "devices": [     {       "version" : "1.2.1",       "name" : "Light Sensor",       "address" : "3c2538dd-64ed-4a0c-9ed3-14b2219feb11",       "deviceType" : {         "name" : "WeMo UPnP Light Sensor",         "maker" : "WeMo",         "protocol" : "UPnP",         "attributes" : [           {             "name" : "State",             "isControllable" : true,             "parameters" : [               {                 "name" : "Hue",                 "value" : 79,                 "dataType" : "int",                 "max" : 255,                 "min" : 0,                 "step" : 1               },               ...             ]           },           ...         ]       }     },     ...   ] }</pre>
Error Response	<p>Errors are returned as an error packet of type <code>0x00</code></p> <pre>00 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX:</b> Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY:</b> Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD:</b> The response to the status request</li> </ul> <pre>{   "error" : "Invalid request" }</pre>

Device Information

Title	<b>Request Device Status</b> Return the state of a device in the system
Destination	The message must be addressed to the device of interest
Message	<div>02 XX XX XX XX YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ PAYLOAD</div> <ul style="list-style-type: none"><li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li><li>• <b>YY</b>: Indicates the bytes of the sender's address</li><li>• <b>ZZ</b>: Indicates the bytes of the device address</li><li>• <b>PAYLOAD</b>: The body of the message</li></ul> <div>{   "get" : "status" }</div>
Success Response	<p>Below is an example of a successful response.</p> <div>04 XX XX XX XX ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</div> <ul style="list-style-type: none"><li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li><li>• <b>YY</b>: Indicates the bytes of the original sender's address</li><li>• <b>ZZ</b>: Indicates the bytes of the original device address</li><li>• <b>PAYLOAD</b>: The state of the device</li></ul> <div>{   "version"      : "1.2.1",   "name"         : "Light Sensor",   "address"      : "3c2538dd-64ed-4a0c-9ed3-14b2219feb11",   "deviceType"   : {     "name"        : "WeMo UPnP Light Sensor",     "maker"       : "WeMo",     "protocol"    : "UPnP",     "attributes"  : [       {         "name"      : "State",         "isControllable" : true,         "parameters" : [           {             "name"    : "Hue",             "value"   : 79,             "dataType" : "int",           },           ...         ],       },       ...     ],   },   ... }</div>
	<p>Errors are returned as an error packet of type <code>0x00</code> . Note: this response example originates from the hub as there is no device with the given address</p> <div>00 XX XX XX XX 00 00 00 00 00 00 00 00 00 00 00 00 00 00 YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</div> <div>XX YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</div>

Error Response	<ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>PAYLOAD</b>: The response to the status request</li> </ul> <pre>{   "error" : "Unknown device" }</pre>
----------------	---

## Control Device

Title	<b>Control Device Attribute</b> Changes the state of a device by passing parameters to a desired attribute
Destination	The message must be addressed to the device of interest
Message	<pre>02 XX XX XX XX YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the sender's address</li> <li>• <b>ZZ</b>: Indicates the bytes of the device address</li> <li>• <b>PAYLOAD</b>: The body of the message</li> </ul> <pre>{   "set" : "attribute name"   "value" : [     {       "name" : "parameter 1",       "value" : "new value"     }     ...   ] }</pre>
Success Response	<p>Below is an example of a successful response.</p> <pre>03 XX XX XX XX ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD</pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>ZZ</b>: Indicates the bytes of the original device address</li> <li>• <b>PAYLOAD</b>: If the device has been updated</li> </ul> <pre>{   "response" : "attribute name",   "value" : {     "device" : "Temperature Sensor",     "deviceType" : "ZigBee Temperature Sensor",     "attribute" : {       "name" : "State",       "parameters" : [         {           "name" : "State",           "value" : 30,           "dataType" : "float"         }         ...       ]     }   ] }</pre>

	<pre>} </pre>
Error Response	<p>Errors are returned as an error packet of type <code>0x00</code> .</p> <pre> 00 XX XX XX XX ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ ZZ YY YY YY YY YY YY YY YY YY YY YY YY YY YY YY PAYLOAD </pre> <ul style="list-style-type: none"> <li>• <b>XX</b>: Indicates the bytes of the PAYLOAD length</li> <li>• <b>YY</b>: Indicates the bytes of the original sender's address</li> <li>• <b>ZZ</b>: Indicates the bytes of the original device address</li> <li>• <b>PAYLOAD</b>: The response to the control request</li> </ul> <pre> {   "error" : "Bad parameter value 'parameter 1':new value" } </pre>

## J-2 Database Interface

### General

This interface provides a way for components in our system to query the database using the defined methods. Any component which has an instance of the Retriever class has access to these methods. A combination of prepared statements and having the database only accessed through an instance of Retriever eliminates the possibility of SQL injection, protecting our system.

### Setup Instructions

To test this interface, there must be an existing database populated with event records. Accomplishing this through our system is a fairly comprehensive task. A database can be created by passing the desired name to the Database class. The created database will initially be empty. To populate it, devices must be created and registered to the hub. Events then need to be generated from these devices, sent through the system, and logged in the database. At this point, this interface is ready to be tested.

An alternative to this is to create and populate a test database manually. An instance of Retriever could be contained by a stubbed component and this interface could then be tested.

### Interface Documentation

#### Event Window

Title	<b>Get Recent Events Across All Devices in a Window</b> Allows the retrieval of a list of events starting from a specified index, ignoring events from specific devices if desired.
Data Params	<ul style="list-style-type: none"> <li>• <b>start</b> : Index in the database to start retrieving from, with 0 being the most recent record</li> <li>• <b>count</b> : Number of events to retrieve</li> <li>• <b>ignore</b> : A list of device UUID's. Any events generated by a device with a UUID in this list will be ignored.</li> </ul>
Sample Response	<ul style="list-style-type: none"> <li>• <b>type</b> : List of dictionaries representing table records</li> </ul> <pre> [   {     "id"      : 2,     "timestamp" : "2016-11-26 22:59:52",     "request"  : 3,     "source"   : "123e4567-e89b-12d3-a456-426655440000",     "change"   : {       "id"      : 4,       "parameter" : {         "id"      : 2,         "attribute" : 18,         "data_type" : "color"       },       "value" : "#F5F6AC"     }   }   ... ]</pre>
Sample Call	<code>getEventWindow(5, 10, [])</code>

## Device Events

Title	<b>Get Recent Events for One Device in a Window</b> Allows the retrieval of a list of events starting from a specified index, ignoring events from specific devices if desired.
Data Params	<ul style="list-style-type: none"> <li>• <b>id</b> : UUID of device to get events from</li> <li>• <b>start</b> : Index in the database to start retrieving from, with 0 being the most recent record</li> <li>• <b>count</b> : Number of events to retrieve</li> </ul>
Sample Response	<ul style="list-style-type: none"> <li>• <b>type</b> : List of dictionaries representing table records</li> </ul> <pre>[   {     "id"      : 2,     "timestamp" : "2016-11-26 22:59:52",     "request"  : 3,     "source"   : "123e4567-e89b-12d3-a456-426655440000",     "change"   : {       "id"      : 4,       "parameter" : {         "id"      : 2,         "attribute" : 18,         "data_type" : "color"       },       "value" : "#F5F6AC"     }   },   ... ]</pre>
Sample Call	<code>getDeviceEvents("123e4567-e89b-12d3-a456-426655440000", 10, 5)</code>

### J-3 Gateway REST API

#### General

The gateway interface provides a public interface for controlling the Aria system using HTTP. The gateway uses a REST protocol for requesting or controlling static data about the system. For dynamic data, the gateway uses websocket messages. Below is the public REST API for the gateway. To see the available events over websockets [see gateway websocket events](#).

#### Endpoint Documentation

##### Discovery

Title	<b>Start Device Discovery</b> This method initiates the discovery sequence for all adapters in the central hub. The return from this call will indicate if the process has started but not if any devices have yet been discovered. All device discoveries will be returned over websocket messages ( <a href="#">see device discovered</a> ) for more details.
URL	/hub/discover
Method	GET
URL Params	None
Data Params	None
Success Response	<b>Example:</b> <b>Code:</b> 200 <b>Content:</b> { }
Error Response	<b>Example:</b> <b>Code:</b> 500 Internal Server Error <b>Content:</b> { error : "Unable to initiate discovery" }
Sample Call	curl -X GET http://localhost:8080/hub/discover

### Hub State

Title	<b>Get Hub State</b> Returns the current state of the hub. This will return the mode, number of connected devices and version of the hub.
URL	/hub/state
Method	GET
URL Params	None
Data Params	None
Success Response	<b>Example:</b> <b>Code:</b> 200 <b>Content:</b> <pre>{   "version" : "1.0.0",   "mode"    : 1,   "name"    : "Smart Hub",   "devices" : 8 }</pre>
Error Response	<b>Example:</b> <b>Code:</b> 400 Bad Request <b>Content:</b> { error : "Invalid Request" }
Sample Call	curl -X GET http://localhost:8080/hub/state

### Hub Mode

Title	<b>Get Hub Mode</b> Returns the mode of the hub
URL	/hub/mode
Method	GET
URL Params	None
Data Params	None
Success Response	<b>Example:</b> <b>Code:</b> 200 <b>Content:</b> { "mode" : 1 }
Error Response	<b>Example:</b> <b>Code:</b> 400 Bad Request <b>Content:</b> { error : "Invalid request" }
Sample Call	curl -X GET http://localhost:8080/hub/mode

Title	<b>Set Hub Mode</b> Update the mode of the hub
URL	/hub/mode
Method	POST
URL Params	None
Data Params	<ul style="list-style-type: none"> <li><b>mode:</b> The new mode of the hub (one of 0 = Standby, 1 = Normal, 2 = Learning )</li> </ul> <b>Example:</b> Set mode to <i>Learning</i> <b>Content:</b> { "mode" : 2 }
Success Response	<b>Example:</b> <b>Code:</b> 200 <b>Content:</b> { "mode" : 2 }
Error Response	<b>Example:</b> <b>Code:</b> 400 Bad Request <b>Content:</b> { error : "Invalid mode" }
Sample Call	<b>Example:</b> Set the mode to <i>Normal</i> <pre>curl -X POST http://localhost:8080/hub/mode \ -H 'Content-Type: application/json' \ --data '{ "mode" : 1}'</pre>

## Event Log

Title	<b>Get Event Log</b> Returns an event window from the hub of the requested window in reverse order (ensuring that the most recent event is first).
URL	/hub/events
Method	POST
URL Params	None
Data Params	<ul style="list-style-type: none"> <li><b>start:</b> The index of the record to start at (0 indicates the most recent record).</li> <li><b>count:</b> The number of records to include in the window</li> </ul> <p><b>Example:</b> Retrieve the last 10 events</p> <p><b>Content:</b></p> <pre>{   "start" : 0,   "count" : 10 }</pre>
Success Response	<p>Upon successful response, the requested records will be returned. The records will be ordered from most recent to least recent.</p> <p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b></p> <pre>{   "records" : [     {       "index"      : 10,       "timestamp"  : 1480262533722,       "device"     : "Temperature Sensor",       "deviceType" : "ZigBee Temperature Sensor",       "attribute"  : {         "name"      : "State",         "parameters" : [           {             "name"    : "State",             "value"   : 30,             "dataType" : "float"           }           ...         ]       }     }     ...   ] }</pre>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Invalid event window" }</p>
Sample Call	<p><b>Example:</b> Retrieve a window of 10 records starting after 10</p> <pre>curl -X POST http://localhost:8080/hub/events \ -H 'Content-Type: application/json' \ --data '{ "start" : 10, "count" : 10 }'</pre>

## Device List

Title	<b>Get Devices</b> Returns a listing of all devices in the system
URL	/device/list
Method	GET
URL Params	None
Data Params	None
Success Response	<p>Upon successful response, all devices will be returned.</p> <p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b></p> <pre> {   "devices": [     {       "version"      : "1.2.1",       "name"         : "Light Sensor",       "address"      : "3c2538dd-64ed-4a0c-9ed3-14b2219feb11",       "deviceType"   : {         "name"       : "WeMo UPnP Light Sensor",         "maker"      : "WeMo",         "protocol"    : "UPnP",         "attributes" : [           {             "name"           : "State",             "isControllable" : true,             "parameters"    : [               {                 "name"       : "Hue",                 "value"      : 79,                 "dataType"   : "int",                 "max"        : 255,                 "min"        : 0,                 "step"       : 1               },               ...             ]           },           ...         ]       }     },     ...   ] } </pre>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Failed request" }</p>
Sample Call	curl -X GET http://localhost:8080/device/list

## Device Events

Title	<b>Get Device Event Log</b> Returns an event window of logs from a specific device in reverse order (ensuring that the most recent event is first).
URL	/device/:id/events
Method	POST
URL Params	<ul style="list-style-type: none"> <li><b>id:</b> The id of the device to request the logs for (ex. 3c2538dd-64ed-4a0c-9ed3-14b2219feb11 )</li> </ul>

Data Params	<ul style="list-style-type: none"> <li>• <b>start</b>: The index of the record to start at (0 indicates the most recent record).</li> <li>• <b>count</b>: The number of records to include in the window</li> </ul> <p><b>Example:</b> Retrieve the last 10 events</p> <p><b>Content:</b></p> <pre>{   "start" : 0,   "count" : 10 }</pre>
Success Response	<p>Upon successful response, the requested records will be returned. The records will be ordered from most recent to least recent.</p> <p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b></p> <pre>{   "total"      : 100,   "records"    : [     {       "index"       : 10,       "timestamp"    : 1480256989762,       "device"       : "Light Sensor",       "deviceType"   : "Aeon Labs UPnP Light Sensor",       "attribute"    : {         "name"       : "State",         "parameters" : [           {             "name"      : "State",             "value"      : 69,             "dataType"   : "time",             ...           }         ]       }     }     ...   ] }</pre>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 400 Bad Request</p> <p><b>Content:</b> { error : "Unknown device" }</p> <p>OR</p> <p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Invalid event window" }</p>
Sample Call	<p><b>Example:</b> Retrieve a window of 10 records starting after 10 for device with id 3c2538dd-64ed-4a0c-9ed3-14b2219feb11</p> <pre>curl http://localhost:8080/device/3c2538dd-64ed-4a0c-9ed3-14b2219feb11/events \ -X POST -H 'Content-Type: application/json' \ --data '{ "start" : 10, "count" : 10 }'</pre>

## Device Values

Title	<b>Set Device Attribute</b> Sets the value of an attribute of a device
URL	/device/:id/setAttribute
Method	POST
URL Params	<ul style="list-style-type: none"> <li><b>id</b>: The id of the device to set the attribute for (ex. 3c2538dd-64ed-4a0c-9ed3-14b2219feb11 )</li> </ul>
Data Params	<ul style="list-style-type: none"> <li><b>name</b>: The name of the attribute to set</li> <li><b>value</b>: A list of parameters and their values for the attribute</li> </ul> <p><b>Example:</b> Set the brightness of a light</p> <p><b>Content:</b></p> <pre>{   "name" : "brightness",   "value" : [     { "name" : "level", "value" : 50 }     ...   ] }</pre>
Success Response	<p>Upon successful response, value of the updated attribute will be returned</p> <p><b>Example</b></p> <pre>{   "response" : "brightness",   "device" : "Light Bulb",   "deviceType" : "Aeotec Dimmable LED",   "attribute" : {     "name" : "brightness",     "parameters" : [       {         "name" : "level",         "value" : 50,         "dataType" : "byte",       }       ...     ]   } }</pre>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 400 Bad Request</p> <p><b>Content:</b> { error : "Unknown device" }</p> <p>OR</p> <p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Invalid data format" }</p>
Sample Call	<p><b>Example:</b> Set the brightness value of device with id 3c2538dd-64ed-4a0c-9ed3-14b2219feb11</p> <pre>curl http://localhost:8080/device/3c2538dd-64ed-4a0c-9ed3-14b2219feb11/setAttribute \ -X POST -H 'Content-Type: application/json' \ --data '{ "name" : "brightness", "value" : [{"level" : 50} ]}'</pre>

Add Behaviour

Title	<b>Add Behaviour</b> This method creates a new behaviour that can be trained.
URL	<code>/hub/training/behaviour</code>
Method	<b>POST</b>
URL Params	<b>None</b>
Data Params	<ul style="list-style-type: none"> <li><b>name:</b> The name to give to the new behaviour</li> </ul> <b>Example</b> <pre>{   "name" : "Turn lightbulb on" }</pre>
Success Response	<b>Example:</b> <b>Code:</b> <code>200</code> <b>Content:</b> <code>{ "id" : &lt; integer &gt; }</code>
Error Response	<b>Example:</b> <b>Code:</b> <code>500 Internal Server Error</code> <b>Content:</b> <code>{ error : "Failed to add behaviour" }</code>

#### List Behaviours

Title	<b>List Behaviours</b> This method returns a paged list of existing behaviours.
URL	/hub/training/behaviours
Method	GET
URL Params	None
Data Params	<ul style="list-style-type: none"> <li><b>start</b>: The id of the behaviour to start from</li> <li><b>count</b>: The number of records to return</li> </ul> <p><b>Example</b></p> <pre>{   "start" : 5   "count" : 15 }</pre>
Success Response	<p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b></p> <pre>{   "records": [{     "id"      : 1 ,     "name"    : "My Behaviour",     "createdAt" : 1380269867612,     "lastUpdated" : 1480256989762,     "active"   : false   }   ...   ] }</pre>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Could not fetch behaviours" }</p>

## List Training Sessions

Title	<b>List Training Sessions</b> This method returns a paged list of existing training sessions.
URL	/hub/training/sessions
Method	GET
URL Params	None
Data Params	<ul style="list-style-type: none"> <li><b>start</b>: The id of the session to start from</li> <li><b>count</b>: The number of records to return</li> </ul> <p><b>Example</b></p> <pre>{   "start" : 5   "count" : 15 }</pre>
Success Response	<p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b></p> <pre>{   "records": [{     "id"      : 1 ,     "name"    : "My Session",     "createdDate" : 1380269867612,     "active"   : false   }   ...   ] }</pre>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Could not fetch training sessions" }</p>

#### Add Training Session

Title	<b>Add Training Session</b> This method creates a new training session for a behaviour
URL	/hub/training/session
Method	<b>POST</b>
URL Params	<b>None</b>
Data Params	<ul style="list-style-type: none"> <li><b>name:</b> The name to give to the training session</li> <li><b>behaviourId:</b> The id of the behaviour to associate with the session</li> </ul> <p><b>Example</b></p> <pre>{   "name"      : "Wednesday Session",   "behaviourId" : 2 }</pre>
Success Response	<p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b> { "id" : &lt; integer &gt; }</p>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Failed to add session" }</p>

#### Start Training Session

Title	<b>Start Training Session</b> This method activates a training session. New events and user requests will be associated with the training session
URL	/hub/training/session/<id>/start
Method	<b>POST</b>
URL Params	<ul style="list-style-type: none"> <li><b>id:</b> The id of the training session to start</li> </ul>
Data Params	<b>none</b>
Success Response	<p><b>Example:</b></p> <p><b>Code:</b> 200</p> <p><b>Content:</b> { }</p>
Error Response	<p><b>Example:</b></p> <p><b>Code:</b> 500 Internal Server Error</p> <p><b>Content:</b> { error : "Failed to add session" }</p>

#### Stop Training Session

Title	<b>Stop Training Session</b> This method deactivates an active training session. New events and requests will no longer be associated with this training session.
URL	hub/training/session/<id>/stop
Method	<b>POST</b>
URL Params	<ul style="list-style-type: none"> <li><b>id:</b> The id of the training session to stop</li> </ul>
Data Params	<b>none</b>
Success Response	<b>Example:</b> <b>Code:</b> 200 <b>Content:</b> { }
Error Response	<b>Example:</b> <b>Code:</b> 500 Internal Server Error <b>Content:</b> { error : "Failed to add session" } OR <b>Example:</b> <b>Code:</b> 400 Bad Request <b>Content:</b> { error : "Training session is not active" }

## J-4 Gateway Websocket Protocol

### General

This websocket protocol provides push events for clients listening to the gateway events. These events notify when a device has been added or an event has occurred. They can be used to observe the system. Currently there is no plan for adding push back over the sockets for dynamic control.

### Endpoint Documentation

#### Device Discovered

Title	<b>Event: Device Discovered</b> Triggered when the hub discovers a new device in the network. This event typically follows a request for discovery but can be manually initiated by adding a device to the network.
Event Name	device.discovered
Data Params	<p>The callback value will be the device that is to be added.</p> <p><b>Example:</b></p> <pre> {   "version"      : "1.2.1",   "name"         : "Light Sensor",   "address"      : "3c2538dd-64ed-4a0c-9ed3-14b2219feb11",   "deviceType"   : {     "name"       : "WeMo UPnP Light Sensor",     "maker"      : "WeMo",     "protocol"   : "UPnP",     "attributes" : [       {         "name"       : "State",         "isControllable" : true,         "parameters" : [           {             "name"      : "Hue",             "value"     : 79,             "dataType"  : "int",             "max"       : 255,             "min"       : 0,             "step"      : 1           },           ...         ]       },       ...     ]   },   ... } </pre>

#### Device Event

Title	<b>Event: Device Event</b> Triggered any time a device changes state through the change in a parameter value
Event Name	device.event
Data Params	<p>The callback value will be the device that is to be added.</p> <p><b>Example:</b></p> <pre> {   "timestamp"    : 1480256989762,   "device"       : "Light Sensor",   "deviceType"   : "Aeon Labs UPnP Light Sensor",   "attribute"    : {     "name"       : "State",     "parameters" : [       {         "name"      : "State",         "value"     : 69,         "dataType"  : "time",       },       ...     ]   },   ... } </pre>

## K System Data

### K-1 Z-Wave Device Data

A full representation of the python object for a zwave device from the openzwave library is below.

## L Project Progress

This section outlines the details about the implementation of the Aria system. It is a record of the major decisions made in the implementation of the system as well as a record of the progress of the development. The details of the project includes the original proposed timeline for the development of the system with a comparison to the true timeline.

### L-1 Proposed Timeline

At the beginning of the project, the development of the project was planned in a week to week plan. This development plan had fairly restrictive timelines and did not leave much room for error. The table below is the originally proposed timeline.

Milestone	Date
Arduino micro-controller hooked up to voltage relay	October 5, 2016
Central server communication with light sensor values	October 12, 2016
Light sensor communication to light controller	October 19, 2016
Arduino motor that moves curtain track	October 26, 2016
Add communication to curtain Arduino	November 2, 2016
Web API	November 9, 2016
Static functioning web interface	November 16, 2016
Add temperature control buttons	November 23, 2016
Add temperature device communication	November 30, 2016
Add basic decision making software	December 7, 2016
Add device discovery	January 2, 2017
Improved web client	January 11, 2017
Improved decision making	January 18, 2017
Add record and learn	January 25, 2017

It quickly became evident that this timeline was too rigid and was not representative of the true development of the project. At the beginning of October, the vision of the project was more formally defined with a much clearer end goal for the project. After the project had been more formally defined, the original timeline was no longer representative of the goals set for the project.

In order to properly plan the development with these new goals in mind, the timeline had to be revised. The new timeline for the project does not rely on dates for individual tasks but instead has set milestones with dates and the tasks that need to be completed for that milestone. Below is the revised timeline for the project. The first milestone includes the requirements elicitation which was formalization of the project goals.

Milestone	Date
<b>Requirements Elicitation</b>	October 12, 2016
Discovery of devices	
Basic control of devices	
Device displayed in user interface	
Event recording in database	
Events displayed in user interface	
Device control from the user interface	
Basic decision system	
User interface control for basic decisions	
Discovery of devices from user interface	
<b>Oral Presentation Demonstration</b>	January 27, 2017
Automated machine learning model builder	
Decision making software to apply model	
Light scenario complete	
Temperature scenario complete	
Coffee scenario complete	
<b>Poster Fair</b>	March 17, 2017

This new timeline defines three major milestones that represent concrete deliverable times for the project. The intermediate goals are all required to be completed before their respective milestone. To ensure that the project is remaining on schedule, this timeline is reviewed on a weekly basis and used to schedule and prioritize project tasks.
